1 INTRODUCTION

1.1 GENERAL

Gilgit-Baltistan of Pakistan is blessed with abundant renewable hydropower resources. More than 95% of Pakistan hydel potential is located in mountainous areas of Gilgit-Baltistan (Gilgit-Baltistan), Khyber Pakhtunkhwa (KPK) and Azad Jammu and Kashmir (AJK). The reconnaissance study of hydel potential for whole Gilgit-Baltistan is almost complete, and identified potential sites are still to be optimized in terms of capacity, cost and need of power for growing load centres. A study for identification and ranking of potential sites on tributaries of Indus river was carried out during 1992 to 1997. Out of 122 identified sites, 17 promising sites were selected to meet local/regional power demand of Gilgit-Baltistan.

On Nov, 2015 Prime Minister announced the construction of Attabad Lake Hydropower Project (ALHPP), Accordingly Govt. of Gilgit-Baltistan undertook its Feasibility Study through Annual Development Programme (ADP) for Financial Year 2016-17. In the beginning Feasibility Study of ALHPP of 32.5 MW was carried out by local consultant of Gilgit-Baltistan, Design man Consulting Engineers (Pvt.) Ltd, Islamabad in association with Mountain Infrastructure & Engineering Services Gilgit, in March 2017. On Aug 2017, Ministry of Water and Power had written letter to the Chairman WAPDA to give expert opinion on construction of ALHPP. On July 2019, a meeting was held between Chairman WAPDA and Chief Secretary Gilgit-Baltistan. It was agreed that Feasibility Study would be again carried out by Hydro Planning Organization (HPO), WAPDA because of its expertise in the field of Hydro Power Planning. Water and Power Development Department, Gilgit-Baltistan shared the already carried out Feasibility Study with HPO, WAPDA in Jan 2020. Feasibility Study was examined by HPO, WAPDA and found the proposed layout is designed without diversion works which is essential part for project execution. Therefore, Feasibility Study was again undertaken by HPO, WAPDA for comprehensive Study with additional investigation.

The Central Hunza is located on the right bank of Hunza River, extending from Murtazabad up to Attabad Village (Figure-1). Central Hunza is the hub of tourism in Gilgit-Baltistan. National and international tourists flow remain at peak during summer season. As a result, hotel industry is booming, whereby, other small-scale businesses i.e. transport sector, cottage industry, local markets and automobile workshops are most likely to flourish in the near future. The increase in tourism industry has significantly enhanced the energy demand of the area. The current demand is expected to increase exponentially in the years to come. Furthermore, the area is having multiple business opportunities due to its location on the China Pakistan Economic Corridor (CPEC), which will result in fast growth of economic activities, thus increase in the energy demand being interlinked with each other.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Figure 1-1 Map of Central Hunza (Source: Google Map)

The Gilgit-Baltistan Govt. has developed three hydropower projects on Hassanabad Nullah in Hunza with an installed capacity of 1.9 MW. The electricity from these hydropower projects is supplied to the Central and Lower Hunza through a 11-kV local distribution network. The supply from these hydropower projects is currently not sufficient to meet the existing demand, therefore it is supplemented through standby diesel generators of 3.2 MW installed capacity during peak hours, mostly in winter season. Due to abrupt surge of Shishper Glacier situated in the catchment of Hasanabad Nullah, the powerhouses on Hassanabad Nullah are under the threat of glacier lakes outburst flood (GLOF). Therefore, it is necessary to develop projects on other water resources to facilitate central Hunza.

In addition to this, there exists a community-owned hydropower project of 0.450 MW capacity on Ahmadabad stream, which is managed and operated by a Community based Public Utility Company in Ahmadabad village. This community owned and operated hydropower project is currently supplying electricity to village Ahmedabad, Altit, Mominabad, Faizabad, and Salmanabad in Central Hunza. The Ahmadabad community-owned Public Utility Company is currently refurbishing and upgrading another hydropower project with 0.370 MW capacity, which is in cascade with the existing hydropower project.

Meanwhile, the Water & Power Department (W&PD), Hunza has completed another 0.5 MW hydropower Project at village Mayans in Lower Hunza. This Project will feed into the existing 11-kV distribution network of Hunza. Furthermore, Gilgit-Baltistan Govt. has conducted a Feasibility Study of a 32.5 MW hydropower project at Attabad Lake requested WAPDA for its updation. Presently, there is high supply and demand gap; therefore, load shedding is common in summer, while it becomes very acute in winter. The commercial and industrial demand is partly fulfilled from privately owned diesel generators. The diesel generators are mainly used by the hotels, small businesses, banks and other consumers which can afford the high running cost. Apart from the cost the use of these diesel generators is creating environmental pollution (i.e. noise and air), which is also affecting the tourism in the area.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The expected fast growth in tourism industry will immensely increase the electricity demand in future, if not planned properly and addressed timely, it will most likely create a crisis like situation in the near future. The shortage of electricity in Central Hunza and vulnerability of Hasanabad Hydropower Projects from any untoward situation of GLOF and normal floods is further increasing the risk of energy crisis in this area.

The Govt. has limited resources to address the issue of sustainable electricity supply in the area. The private sector is reluctant to invest in Gilgit-Baltistan's energy sector, which is due to absence of a Power Policy and non-connectivity of the area with the National Grid. The Power Policy of Gilgit-Baltistan Govt. is currently under appraisal and approval. Aga Khan Development Network (AKDN) institutions are supplementing and complimenting the efforts of the Govt. in Gilgit-Baltistan. Small scale micro hydels have been established in remote off-grid rural areas from donor funding, while urban centres like central Hunza are beyond their scope.

The Industrial Promotion Services (IPS)/NPAK Energy is collaborating with the Govt. of Gilgit-Baltistan to improve the distribution system of Central Hunza by replacing bare AAC/ACSR conductors by ABC Cable. Considering the energy shortage in central Hunza, they intend to develop hydropower project(s) in the area to address the energy crisis. The Govt. of Gilgit-Baltistan has already indicated a concession area (from Ganish Bridge to Salmanabad village) on Hunza River to IPS/NPAK Energy to study the prospects for development of hydropower projects.

Govt. of Gilgit-Baltistan has engaged WAPDA (HPO) to update the Feasibility Study of 32.5 MW ALHPP. WAPDA is using its in-house capacity to review Feasibility Study. After thorough field investigations WAPDA has updated the proposed installed capacity to 54 MW with a 2320 m long headrace low pressure tunnel on the left side of Hunza River. The tunnel will off take from the left bank upstream of existing outlet of Attabad Lake. For this fields investigations have been carried out.

Attabad Lake was formed on January 4, 2010, when a huge mass from the right bank of Hunza River slided down near Attabad Village and blocked Hunza River for about 2 km . The inflow filled upstream valley created a reservoir 22 km long till the end of May 2010. The estimated lake initial storage was about 310 million m^3 and presently its capacity reduced to 125 million m^3.

For drainage of impounded flows of Hunza River through slided area, the excavation of material was carried out (24 m deep and 45 m wide) to form as spillway. The excavation works for the spillway was completed in the mid of May and the overflow of River flow began on May 29, 2010. The pattern of outflows was observed at downstream Ganish Bridge. The flows in summer 2010 were as a result of snow melt, no abrupt change in flows observed till to date.

Extensive field reconnaissance, topographical survey, hydrological and geo-technical investigations and engineering studies have been carried out for updating the Feasibility Study, in order to establish a Project that could provide power supply from Hunza Valley to Gilgit and Sost.

ALHPP (54 MW) has been planned to meet the winter power demand of Hunza Valley by utilizing the peaking storage facility at existing Attabad Lake. The installed power would remain available throughout the year during peak hours. As a result of the assessment of field investigations and engineering studies, it is concluded that the Project of 54 MW is technically,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

economically feasible and environmentally safe. The Project can further enhance due to available potential at the location of Hunza River once the Regional and National Grids established.

The most promising project layout as assessed is located at the Attabad Lake on the left bank of Hunza River at a distance of about 20 km from Karimabad, 120 km from Gilgit and 735 km from Islamabad.

The deep diversion and flushing structures are proposed to be located at the existing outlet/spillway of the Attabad Lake. The weir site is available having narrow span and firm rock strata on right side of River Hunza. The headrace tunnel is proposed along the left bank of the River along existing link road from intake to powerhouse. The powerhouse is located well above the highest flood level. The coordinates of the weir and powerhouse site are as follows:

Overflow Weir/Ungated Spilway:	484036.834 m E	4018143.837 m N	2414 m.a.s.l
Powerhouse:	481645.920 m E	4017963.719 m N	2300 m.a.s.l

The Project area is to be constructed on marginal lands owned by the community of Ahmadabad village where minimum environmental and social issues have been anticipated. The Project google site plan and location map are shown in the Figure 1.2 and Figure 1.3.

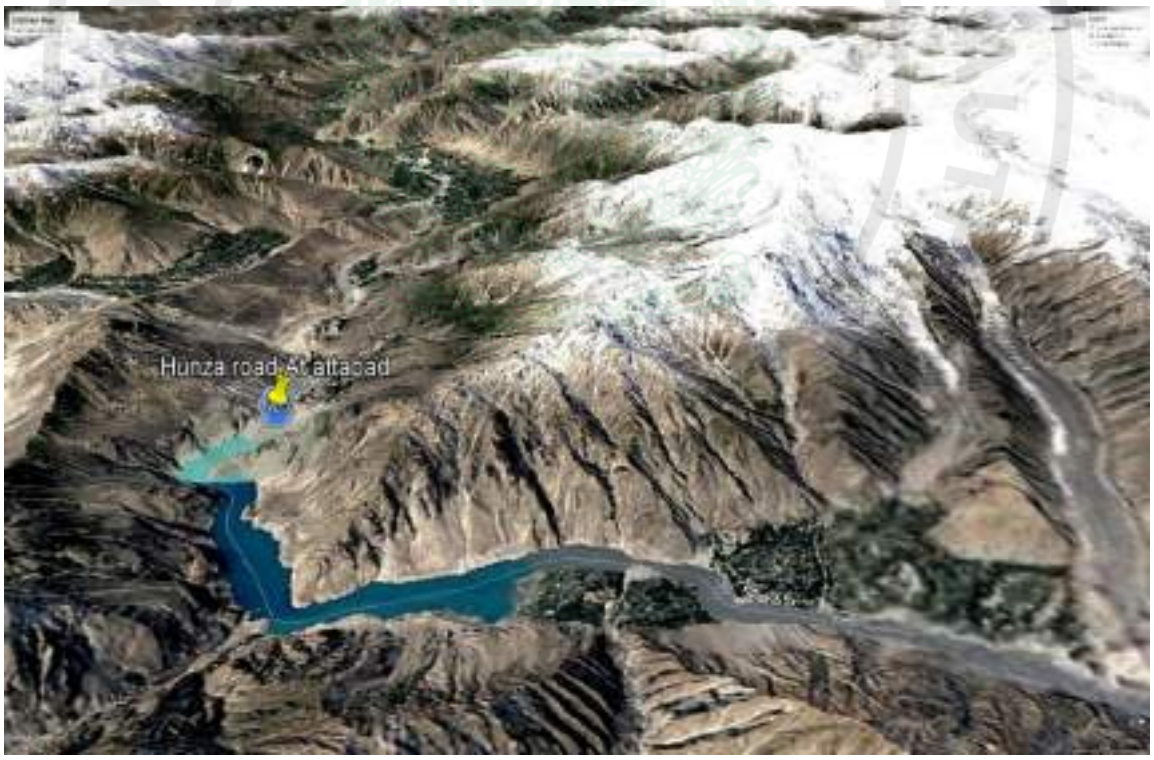

Figure 1-2 Site Plan (Source: Own Compilation from Google)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

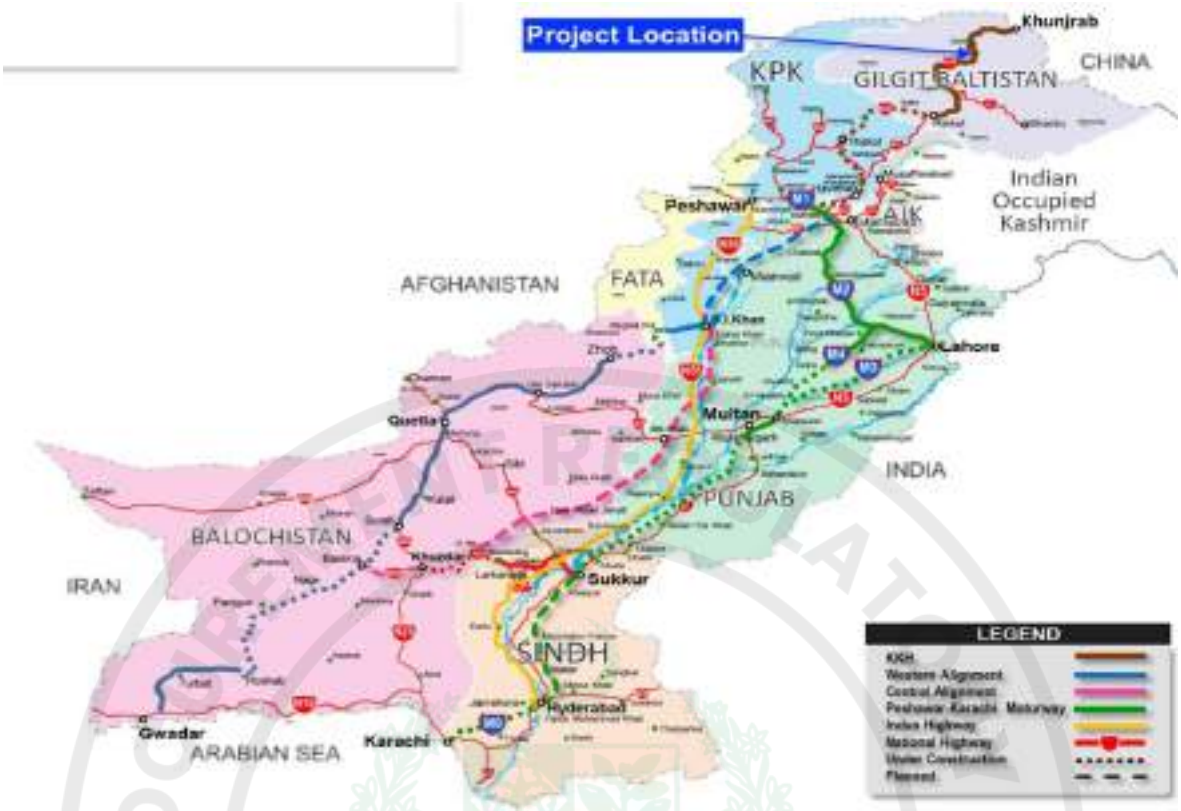

Figure 1-3 Location Map (Source: NHA Pakistan)

1.2 SALIENT FEATURES

ALHPP, a run off river Project, was initially planned to generate about 32.5 MW power in two phases, by diverting the flow of Hunza River, a major tributary of Gilgit River, into a power tunnel and ultimately releasing into Hunza River. This was designed to take care of power and energy needs of the Hunza-Nagar districts for next two decades as an isolated scheme. However, the connection of the Hunza Nagar districts to the Regional Grid makes the Project to be studied for its enhanced potential. A number of alternatives are studied and based upon the conclusions of these studies; it is finally decided to design the scheme for the generation of 54 MW (installed capacity) consisting of three units with an average annual energy of about 374 GWh.

An overflow weir will be constructed to divert the flow of Attabad Lake at Hunza River into power intake. Before construction of weir, a deep sediment flushing channel/ under sluice will be constructed this will act as a diversion channel during construction of weir. After the construction of the Project at operational stage under sluice will act as sediment flushing channel. The diverted water enters into the head race tunnel about 2320 m long. The tunnel is followed by surge shaft. Water will enter into 470 m long penstock pipe branching into three units at the end through manifold. These high-pressure penstock pipes and feed three turbines, 18 MW each.

The Project is proposed to be developed on Hunza River at Attabad Lake with design discharge 60 m^3/s to generate the rated power round the year. This Project will enhance the generation capacity and augment the power supply network of entire Hunza-Nagar Valleys and Gilgit Town.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Once completed and operational this Project will help to improve the power supply situation in the Region.

The Salient features of the envisaged power supply Project are given as follows:

Type of Development:	High Head Run of River with Peaking
Gross Head:	112.0 m
Net Head:	106.0 m
Installed Capacity:	54 MW
Type of Turbine:	Francis (Vertical)
No. of Units:	03
Design Discharge (Qd):	60.00 m^3/s (20 m^3/s to each unit)
Length of Weir:	55 m
Length of Power tunnel:	2320 m
Type of Powerhouse	External
Annual Energy:	374 GWh
Plant Factor:	79 %

1.3 CLIMATE

The climate of the district is nearly dry. The summer season is cool while winter is chilly. Wide spread snow fall occurs in winter. During winter the northern winds blow constantly bringing the temperature down considerably.

At Hunza, the mean temperature is 30.20°C in July, the hottest month and the coldest month is January with an average temperature of -3.5 °C. The mean minimum temperatures are 21.9°C in July and -7.3°C in January respectively. Hunza like other areas in extreme north-west of Pakistan receives only 136 mm precipitation of which 40% occurs in Winter and Spring.

Climate of the Hunza District is moderate with average minimum and maximum temperatures of 16 and 35.9 °C, respectively. The annual average rainfall in the study area is 136.2 mm with minimum 2.1 mm in November and maximum 28.3 mm in April.

1.4 TRANSPORT AND COMMUNICATION

The means of transportation and communication are the necessary infra-structures for movement of goods and people and play a vital role in the economic development of any region.

All the Union Council centers except few are connected with each other by metalled roads, nevertheless, there are certain parts of these roads which must be improved and for transportation during winter, the district remains connected throughout the year with the rest of country through Karakoram Highway (KKH).

There is transportation through KKH between Gilgit, Hunza upto Sost and Khunjrab Pass towards China by buses and trucks. The road is in excellenet condition and asphalted, although the traffic remains suspended due to heavy snowfall during December to March at Khunjerab Pass, which lies at an altitude of about 4693 m.a.s.l. The road is characterized by bends and steep slopes while descending from top to Hunza Valley.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

1.5 ACCESS TO THE PROJECT AREA

The present available access to the Project area by Motorway from Islamabad to Thakot and afterwards by KKH from Thakot to Project Area is very good. Power house site is located on the left bank of Hunza River near Salmanabad Village. Access to the Project Site, along the Attabad Lake is very easy with steep slopes and moderate bends. It will not create problem with the transportation of heavy construction and permanent equipment for the Project as well as the heavy construction materials. These difficulties may significantly affect the overall construction schedule. However, the road towards Power House Site needs improvement involving rock blasting and widening of the track to cater for the transportation of the heavy construction material and machinery.

1.6 EXISTING POWER SUPPLY

The present installed capacity of hydropower and thermal power stations is 5.6 MW for peak hours. Although the consolidated installed capacity of Hassanabad hydropower projects is 1.9 MW, but over the time, the efficiency of these projects have reduced due to high amount of silt in the Hassanabad Nullah, resulting in regular need for overhauling of the turbines at least twice a year. The diesel generators with a consolidated installed capacity of 3.2 MW are used as standby. These diesel generators are operated during peak hours only, and are subject to the availability of funds for purchase of fuel & oil for their operation. The list of projects in district Hunza which are under operations, under construction and proposed are given in the Table-1.2

The available output from the existing hydropower stations and diesel generators is evacuated through 11-kV lines to the load centers. Further distribution is made after stepdown through 11/400-kV transformers and 400/230 V, LV distribution lines. The existing 11-kV distribution system is overloaded resulting in high voltage drops, especially at the end users' premises. The technical losses are very high and accounted for more than 30%. Hence, the net supply available for the consumers is well below the installed capacity.

At present the conservative demand of Central Hunza is estimated at being 7.0 MW during summer and 10 MW in winters. However, the optimistic demand of consumers is estimated as 12 MW during summer and 18 MW in winter season, details of which has been given in the Chapter No-3 "Power Market & Demand Forecast".

In Gilgit-Baltistan, most of the power generation, transmission and distribution system is being maintained and operated by Water & Power Deptt. Gilgit-Baltistan.

1.7 ADMINISTRATIVE ORGANIZATION

Hunza is one of the fourteen districts constituting the Gilgit-Baltistan of Pakistan. The highest administrative authority is the Deputy Commissioner, who is assisted by Assistant Commissioners of two sub-divisions. Administratively, the Hunza District comprises two tehsils, the Aliabad Tehsil and the Gojal Tehsil. The villages of lower Hunza and central Hunza are located in the Aliabad Tehsil, whereas the villages from the Attabad Lake up to the Khunjerab Passare located in the Gojal Tehsil. In lower Hunza, Shinais the main language, whereas in central Hunza, the dominant language is Burushashki, and in upper Hunza, Wakhiis the main language. District administration is exercised by the Deputy Commissioner (DC), with the assistance of an assistant commissioner. The Hunza police force is commanded by the Superintendent of Police (SP).

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

These institutions have technical support of various departments of Govt. of Gilgit-Baltistan in Hunza town such as Communication, Roads, Agriculture, Irrigation, Fishing, Education, Health, Revenue, Food, Social Welfare Office and Forest Division. All are located in Hunza town.

2 POWER MARKET AND DEMAND FORECAST

2.1 INTRODUCTION

An optimized planning for energy load forecasting is always the crucial part to determine future power demand for any developing region. In the power sector, reliable planning/load forecasting is the threshold to cater the future electricity demand. Power Infrastructure design including generation, transmission and distribution can be proposed on a power plan with improvising scenarios. Poor forecasting and planning could be rankled to manage the load demand while precise forecasting could be savvy to overcome the underestimations & overestimations of load management, which avoid financial and social-economic impact.

Thus, power market survey (short, medium and long period Load Forecast) contributes to overcome the energy shortage and facilitate all type of patrons including Residential, Commercials & Industrial.

This chapter describes and evaluates the future power demand in Gilgit-Baltistan, based on figures of the GDP and an expected increase in per capita consumption. For the design of the transmission & interconnection system, this information is advantageous as one of the chief matters for the layout of the Attabad Hydropower Project is to determine the future power demand in the Hunza district and the whole Gilgit-Baltistan.

The Gilgit-Baltistan being far off from National Grid has been facing severe shortages of power supply. Because electricity from fossil fuel is not only expensive moreover it causes pressure on foreign exchange reserves of Pakistan, hydropower being renewable resource constitutes is the best option which needs to be exploited in a rational manner. The tributaries and rivers of Gilgit-Baltistan have been considered for the development of hydropower resources to meet the local energy requirements and eventually to transfer the power to national grid.

2.2 GILGIT-BALTISTAN POWER SECTOR OVERVIEW

Gilgit-Baltistan had ten districts (Gilgit, Ghizer, Nagar, Hunza, Diamer, Astore, Skardu, Ghanche, Shigar and Kharmang).

Figure 2-1 Map of Gilgit-Baltistan

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Power Network System in Gilgit-Baltistan is based on foresaid ten districts. This chapter presents the district wise current Demand, Generation, Energy Deficit & Load Forecast studies of electricity demand from the year 2021 to 2050, a planning horizon of 30 years.

In order to provide electricity to the isolated network of the Gilgit-Baltistan areas, the Northern Areas Public Works Department (NAPWD) was established, which is responsible for the generation and distribution of electricity. The NAPWD is divided into two departments. The Water and Power Department responsible for Hydropower Projects and Public Works Department responsible for roads and infrastructure of the Gilgit-Baltistan area. Water and Power Department has constructed various mini hydropower stations in the region and the lines for the transmission of power to consumers.

2.2.1 Establishment of Regional Grids in Gilgit-Baltistan (Phase-1 & 2)

Water and Power Department of Gilgit-Baltistan has prepared PC-I regarding “Establishment of Regional Grids in Gilgit-Baltistan Phase-1 & 2” wherein the future expansion plan and establishment of regional grids are consisted on 10 valleys of Gilgit-Baltistan based on population and its growth, industrialization and consumption patterns. The model forecasts demand for electricity as the consolidated sum of demands from households of each domestic consumption (divided into three income groups), commercial centers, and public service units and from small industries.

The plan of Establishment of Regional Grids in Gilgit-Baltistan “Phase-I & II” relate to transmission planning, Grid stations & up-gradation of the existing power network of Gilgit-Baltistan. Its objective is to interconnect the following hydropower projects to efficiently utilize the generated electrical energy.

- 18 MW Hydro Power Project Nalter IV.
- 16 MW Hydro Power Project Nalter III.
- 14 MW Hydro Power Project Nalter V.
- 20 MW Hydro Power Project Hanzel Gilgit.
- 34.5 Mw Hydro Power Project Harpo Skardu.
- 80 MW Hydro Power Project Phander Ghizer.
- 100MW Hydro Power Project KIU Gilgit.
- 32.5 MW Hydro Power Project Attabad Hunza (power enhanced upto 54MW)
- 26 MW Hydro Power Project Shagharthang Skardu.

Another purpose of the above plan is to attract private investors to take interest in the development of Hydropower projects to harvest maximum hydro potential. The proposed project of phase1 caters to the power demand in these districts (Gilgit, Hunza/Nagar and Skardu & Astore).

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Existing Regional Grid of Gilgit-Baltistan is not connected with National Grid of Pakistan, mostly small hydro and thermal unit installed by the local Govt. are having the energy contribution to a local level. Large Hydropower projects are in the studies & construction stage which will be committed to meet the national and regional energy crisis.

Different interconnection schemes are under consideration by the NTDCL planning department to interconnect the regional Gilgit-Baltistan grid to National Grid, and to evacuate from the upcoming mega hydropower projects. In future bulk supply will be fed from Mega Hydropower Project i.e. Diamer Basha and Bunji while medium and small hydropower projects i.e. Phandar, Attabad & Harpo to overcome the demand in Gilgit-Baltistan and surplus power after then could be drawn to the national grid.

Hydel is the major contributor in Gilgit-Baltistan to produce electricity. WAPDA and Water and Power Department, Gilgit-Baltistan intend to commission mega to small scale hydropower projects to supply clean and cheap electricity at the regional and national level. Many small and medium hydropower projects have been installed and some are in construction stage while others are in the feasibility & design stage.

32.5 MW Attabad Hydropower Project was also part of the aforesaid plan, but after the revised study being conducted by WAPDA, the project is upgraded upto 54 MW and needs to redefine the Interconnection and power evacuation plan after 1.67 times enhanced power.

2.2.2 Power Generation in Gilgit-Baltistan

The power demand in Gilgit-Baltistan is mostly covered by small hydropower plants (<20 MW). Electrical energy is transmitted over short distances through 66 kV, 33 kV and 11 kV gridlines and is further distributed to the consumers through 400 V LT systems. Due to the geographical boundaries, the existing grid is a regional one with no link to the national grid. Indeed, in the future, it is planned to link the existing regional grid to the national grid. However, this requires the completion of both planned Mega-Projects “Diamer Basha” (in construction stage) and “Bunji” (investors for funding are required to construct the project). In Gilgit-Baltistan, Total 118 nos. power stations have been commissioned with total 194.55 MW installed capacity. Table 2-1 shows the district wise installed power & Figure 2-2 shows the no. of installed power plants in different regions of Gilgit-Baltistan.

Table 2-1 District Wise Installed Power Potential in GILGIT-BALTISTAN

District	Hydel Stations	Thermal Stations	Hydro Power	Thermal Power	Total Installed Capacity
	Nos.	Nos.	MW	MW	MW
Gilgit	19	13	58.37	9.41	67.78
Diamer	10	5	15.48	2.90	18.38
Skardu	19	7	36.90	6.00	42.9
Ghizer	14	3	15.37	0.90	16.27
Ghanche	12	2	11.94	0.40	12.34

2.2.3 Hydropower Potential in Gilgit-Baltistan

The entire region of Gilgit-Baltistan is enriched with natural resources. Nature has blessed Gilgit-Baltistan with minerals, attractive weathers, world high peaks, glaciers, water torrents, rivers & tributaries, sunlight and other natural resources.

Although, Gilgit-Baltistan is producing electricity by two means (Hydel & Thermal) but it has potential to produce electricity from other renewable resources. The Govt. of (GILGIT-BALTISTAN) is also willing to get untainted energy from renewable resources. The inception studies to get power from renewable resources are under progress by Water & Power Dept. Gilgit-Baltistan and will be made part of Power Plan in future.

The main rivers and tributaries in the Gilgit-Baltistan Area have been divided into three regions, i.e. the Eastern, Northern and Southern Regions.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Eastern Region: The Eastern Region comprises on Kharmang (River Kharmang and its tributaries), Shyok (River Shyok and its tributaries), Skardu (River Braldu, River Bashu, River Shigar and River Indus) and Rondu/ Haramosh (River Indus and its regional tributaries).

The Northern Region: Comprises of Gilgit (River Gilgit, River Naltar and its tributaries), Hunza (River Boladas, River Hunza and other tributaries), Ishkuma (River Ishkuman and Ghizar and their tributaries), Khunjerab (River Khunjarab, River Kilik and its tributaries) and Yasin (River Yasin, River Gilgit and their tributaries).

Southern Region: The Southern Region comprises the Chilas (River Indus and its tributaries) and Astore (River Astore and its tributaries) Total 118 Hydel Power Stations are in operation in Gilgit-Baltistan, mostly of projects have been listed in Table 2-2:

2.3 POWER MARKET STUDY CONDUCTED BY WAPDA WITH GTZ

Comprehensive planning of hydropower resources on tributaries of Indus River in Northern Areas was started in July 1992, by Hydro Planning Organization (HPO) before known as Hydro Electric Planning Organization (HEPO) WAPDA, in collaboration with the German Agency for Technical Corporation (GTZ) from the Public Federal Republic of Germany. In the study, project areas were divided into 12 regions which are listed below.

Table 2-5 Surveyed Region

Sr. No	Region	Area
1	Region-3	Gilgit
2	Region-4	Hunza
3	Region-5	Ishkuman
4	Region-6	Yasin

2.3.1 Methodology

Studies were followed the DIPO system, a methodology for technically and economically optimum development of proximal hydropower potentials for regional power development mainly in isolated rural areas, by

- Definition of requirements and Objectives
- Identification of Power Demand and matching Hydro Potential
- Planning of Regional Power Supply Systems
- Execution of the planned installations
- Operation of the systems

The system was developed within different projects of German Technical Cooperation over a period of 17 years; Burundi, Peru and then in Pakistan prepared for Current and Future Development as a permanent dynamic planning instrument.

The study presented the available sources of energy, demand forecast upto the year 2014 for identified potential. Demand Forecast was carried out analytically.

2.3.2 Load Separation

Possible Load (electricity demand) was categorized in two main types;

I. Autonomous Load: The load normally in such areas for domestic, commercial, crafts and public services (DCCP).

II. Promoted Load: Resulting from special incentives etc. given to utilize electricity e.g. for heating, baking and cooking (HBC-Load) to protect forest and /or for prospective development Projects.

2.3.3 Autonomous Load

It is the normal demand of the people which increases with the growth of population, with more people in a locality more power would be consumed. The demand automatically increases due to development in agricultural, industry health facilities educational opportunities communication system. These development activities lead to change in income level and people start using new products and appliances.

The population growth rate was the main determining factor for future load development. As autonomous load is essentially the demand of power of the people in the locality, it is essential to give the basis of growth rate for the years 1994-2004. Taking into consideration the Govt. policies, it is likely that in medium and long (10-20 years) the growth rate was declined. But future rates of growth cannot be defined exactly, and assumptions were made. To make a sensitivity analysis, three alternatives were made.

For estimating the power demand, the autonomous load for power and energy was considered. This load generally develops if electricity is provided to any region. It had three basic characteristics.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Optimistic (High): The increase in population during 1994-2004 was assumed at the same rate as experienced during 1981-94.

Intermediate (Medium): The same growth rate during 1994-2004, but the decrease of 0.5 percent was expected for the next year 10 years from 2004 to 2014.

Conservative (Low): The growth rate is assumed to be decreased by 0.5 per annum during 1994-2004 and it is further declined by 0.5 percent per annum on average from 2004-2014.

Table 2-6 shows the projected load demand from 1994 to 2014, forecasted for all regions.

Table 2-6 Load Forecast Projected by WAPDA & GTZ

2.4 POWER MARKET - PRESENT SCENARIO

Life in Gilgit-Baltistan is predominantly agrarian. Farming has continued to be a major occupation of the people. Agriculture is dependent upon vagaries of climatic conditions as winters are long and harsh. The farm sizes are small, fragmentation is taking place and the household incomes are on a subsistence level. There is the migration of workforce to cities and towns in the down country, and also as far as to Karachi in the south to sustain meager livelihood.

2.4.1 Exploitation of Natural Resources

Agriculture is a major occupation of the people in Gilgit-Baltistan which depends upon whims of climatic conditions as winters are long and harsh. The non-availability of electricity is a major constraint to undertake farm cultivation program on a large scale. There are no cold storage facilities to preserve fruits which can earn substantial income to the orchard growers. Hunza and Nagar valleys have precious mineral resources which have remained unexploited. The incomes are on a subsistence level, thus making pavement for the migration of workforce to cities and towns in the down country to sustain meager livelihood. The availability of electricity will certainly develop a set up on large scale to preserve fruits and for exploration of minerals.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

2.4.2 Tourism

The Gilgit-Baltistan region and its valleys are tourist's paradises for tracking and mountaineering. There is a great potential for business and employment prospects in this sector. At present a few opportunities under Govt.'s social and infrastructure development programs are available for the educated and skilled workforce in various trades. The reliable energy sources and transmission network are key factors for the development tourism and mountaineering.

2.4.3 Trade Route to China

The opening up of Gilgit-Baltistan region to China has provided an incentive to the local entrepreneurs for self-employment and outlets for income generation. This has resulted in job creations for educated young people. Hunza is developing into a central city for economic activities for tourism. With the provision of the basic infrastructural facility of electricity, Hunza and its surrounding towns have the potential for development in the coming years. Sost is the last town of Gojal, Upper Hunza inside Pakistan on the Karakoram Highway before the Khunjerab Border. This town has importance due to the dry port. The Silk Route Dry Port is functional since 2002. Sost dry port is the first formal port at China-Pakistan border, facilitating customs clearance and other formalities for goods moving between China & Pakistan. Currently, this region is also facing the shortfall of electricity and only Misghar power station is installed nearby this town. After commissioning the Attabad Hydro Power Project, current electricity shortfall scenario will be changed and routine trade will be accelerated.

2.4.4 Change in Social Life

Many social and economic changes have taken place at the macro level in the Gilgit-Baltistan region. The people desire to get education and obtain skills in trades and vocations, and also development and improvements in transport and communication have opened new avenues of income generation. The improvement in these sectors has continued to grow with time. The requirements of electricity have increased in homes, both public and private offices, education institutions, hospitals, and health care centers in towns and habitats in the remote rural areas of valleys in Gilgit-Baltistan region.

2.4.5 Investment Incentive

Electric power is a prerequisite to any other investments. Without electricity both human and physical resources will remain unutilized for increasing welfare of the masses for providing income opportunities at or near the level being available to people in the developed part of the country. The elaboration of social, cultural and the people's desire to be prosperous has necessitated the present update of the power demand estimation in the isolated power supply area of Gilgit-Baltistan.

2.4.6 Power Generation, Demand & Shortfall of Districts of Gilgit-Baltistan

According to the statistics provided by Water & Power Division GILGIT-BALTISTAN, the power generation & demand is grouped for two seasons like summer and winter. In the Gilgit region 49 & 33.6 MW produced in summer & winter respectively with demanded power of 49.89 & 94.51 MW. Gilgit has faced the short fall of 0.89 & 60.91 MW. Diamer has produced 10.59 & 10.75 MW while the present demand noted 36.02 & 50.34 MW with the shortfall of 25.43 &

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

39.59 MW. In the Skardu region 20.30 & 16.20 MW produced in summer & winter respectively with demanded power of 50.6 & 94.47 MW. Skardu has faced the short fall of 30.3 & 78.27 MW.

Ghizer has produced 12.50 & 9.38 MW while the present demand noted 38.88 & 71.34 MW with the shortfall of 26.38 & 61.96 MW. In the Ghanche 8.09 & 5.16 MW produced in summer & winter respectively with demanded power of 25.5 & 48.52 MW. Ghanche has faced the short fall of 17.41& 43.36 MW. Astore has produced 4.50 & 4.0 MW while the present demand in 2020 noted 14.83 & 24.53 MW with the shortfall of 10.33 & 20.53 MW. In the Nagar 4.56 & 2.53 MW produced in summer & winter respectively with demanded power of 9.27 & 16.97 MW. Nagar has faced the short fall of 4.71 & 14.44 MW in summer and winter respectively. Hunza has produced 4.71 & 3.58 MW while the present demand noted 12.83 & 20.61 MW with the shortfall of 8.12 & 17.03 MW. In the Shiger 3.50 & 2.0 MW produced in summer & winter respectively with demanded power of 10.35 & 18.36 MW. Shiger has faced the short fall of 6.85 & 16.36 MW in summer and winter respectively. Khermang has produced 4.61 & 4.07MW while the present demand in 2020 noted 6.65 & 12.54 MW with the shortfall of 2.04 & 8.47 MW. The district wise power values are mentioned in Table 2.8.

Table 2-8 Current Power Scenario of Gilgit-Baltistan

District	Present Generation (MW)						Present Demand (MW)		Present Shortfall (MW)	
	Summer			Winter			Summer	Winter	Summer	Winter
	Hydel	Thermal	Total	Hydel	Thermal	Total				
Gilgit	49.00	0.00	49.00	25.80	7.80	33.6	49.89	94.51	0.89	60.91

Khermang	4.61	0.00	4.61	4.07	0.00	4.07	6.65	12.54	2.04	8.47
Total	**120.76**	**1.60**	**122.36**	**75.43**	**15.84**	**91.27**	**254.82**	**452.19**	**132.46**	**360.92**

In figure 2-19, Power scenario is sketched out for the summer 2020, which shows that due to bulk supply of water in summer deficit between demand and generation is less than from winter power scenario which has shown in figure 2-20.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

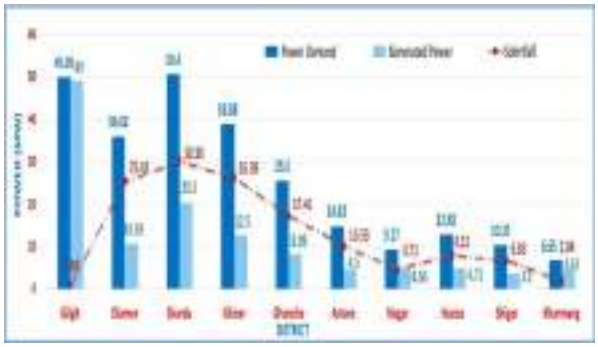

Figure 2-19 District wise Summer Power Scenario in Gilgit-Baltistan

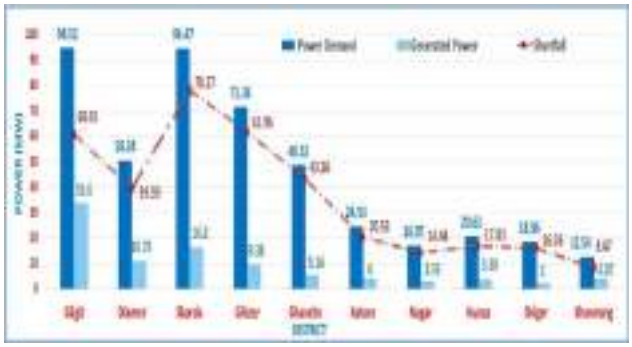

Figure 2-20 District wise Winter Power Scenario in Gilgit-Baltistan

In Figure 2-21, comparison could be easily seen for the power demand in Gilgit-Baltistan for the both season of summer and winter.

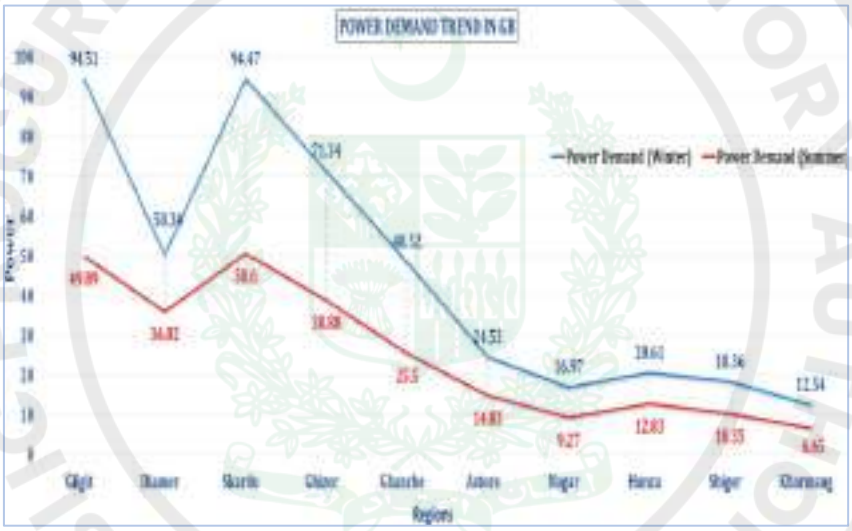

Figure 2-21 District wise Overall Power Demand in Gilgit-Baltistan

2.4.7 Current Power Market HUNZA District

Energy is a critical input for economic development and correspondingly power sector comprises an indispensable infrastructure in any economy. Providing adequate and affordable electric power is essential for economic development, human welfare and better living standards. The growth of the economy along with its global competitiveness hinges on the availability of reliable and quality power at competitive rates to all consumers throughout the country. Electricity is central to achieving economic, social and environmental objective.

Attabad Lake Hydropower Project is located in the Hunza District, it is worthy to discuss the current Power scenario of Hunza district in detail for understanding the imperial impact of project in the region and forecast the demand for the future. The power supply area of the proposed site covers mainly the Upper, Middle and Lower Hunza District. Currently following hydropower projects are operating in Hunza.

11	MHP Shimshal	2017	0.20
		Total	**9.1**

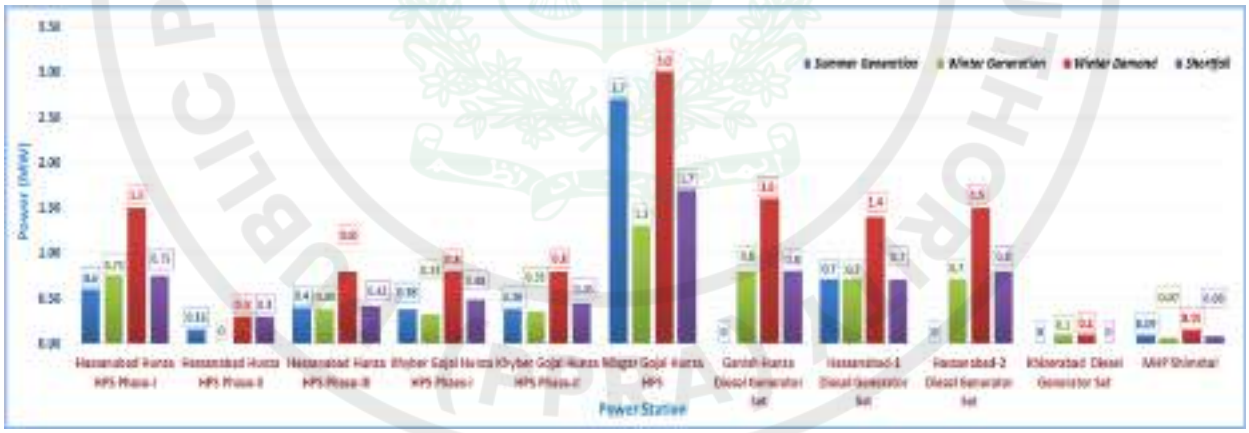

Figure 2-22 Installed Capacity in Hunza

2.4.8 Load Shedding

The per capita consumption of electrical energy depends on various factors of which the most important are:

- No. of consumers connected to the electrical grid - the more consumers are connected to the grid the higher the per capita consumption will beLoad shedding pattern - the per capita consumption will increase with lower load shedding rates No. of electrical devices per consumer - a growing economy results in a higher prosperity what increases the no. of electrical devices per consumer (fridges, air- conditioning, television etc.).

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Industrialization - a growing economy also results in a growing no. of commerce and industry. Thus the per capita consumption also includes industrialization.

The scenario of constricted supply-demand is envisaged to undergo a radical improvement with the execution of the new powerhouses. The availability of electricity for production of goods and commodities will result in higher income generation. This increase in income will raise standard of living of the people who will have an impetus to purchase household electric gadgets and appliances.

In the present situation, Gilgit-Baltistan is facing power shortage. Therefore, load shedding is being carried out as load management in entire region. Hunza is also facing worst power shortage which badly impacts its economy. During the survey in Aliabad and Karimabad which are tourist hubs and have sufficient local population it is conceded that the hoteling and local business have been disturbed badly due to long hour load shedding. The load management schedule of Hunza District is listed as under.

Table 2-10 Load Shedding Hours in Hunza

Project	Supply Area	Status	Current Generation (MW)	Load Management / Schedule (Hours)
Hassanabad Hunza HPS Phase-I	Hassanabad and Aliabad	Operation	0.60	**14**
Hassanabad Hunza HPS Phase-II	-	Un-operational	-	**-**
Hassanabad Hunza HPS Phase-III	Murtazabad to Khiziriabad	Operational	0.7	**14**
Khyber Gojal Hunza HPS Phase-I	Khyber to Nazimabad	Operational	0.380	**22**
Khyber Gojal Hunza HPS Phase-II	Passu to Shiskhat	Operational	0.380	**18**
Misgar Gojal Hunza HPS	Misgar, Sost, Khudabad, Chipurson, Ganish, Garelth, Karimabad, Hyderabad, Dorkan & Rahimabad	Operational	2.6	**22**
Misgar HPS (1.8 kW)		Operational in Winter Season	-	
MHP Shimshal	Shimshal	Operational	0.060	**No load shedding**

2.4.9 Electricity Consumers in HUNZA District

Energy is a critical input for economic development and correspondingly power sector comprises an indispensable infrastructure in any economy. Providing adequate and affordable electric power is essential for economic development, human welfare and better livings.

In this chapter, current consumers of Hunza District have been shown in Figure 2-23. As per administrative record, total population of Hunza, Water & Power Dept. (Gilgit-Baltistan) owns 11416 consumers which are categorized into three main consumer groups shown in below table.

Consumer	Domestic	Commercial	Industrial	Total
Connection	9191	2159	66	11416

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

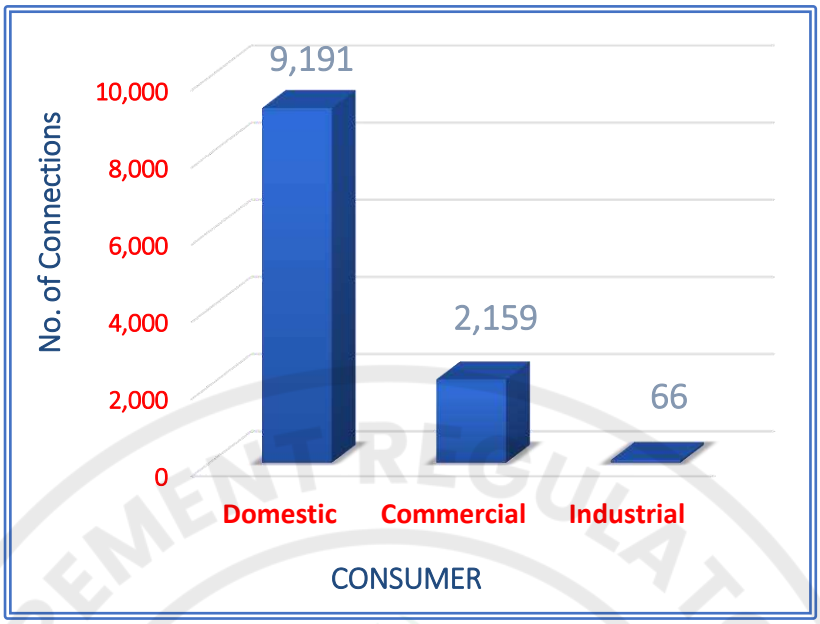

Figure 2-23 Electricity Consumers in Hunza

2.5 POWER DEMAND FORECASTING

2.5.1 Determination and Forecast Power Demand

For a reasonably reliable determination of the power demand, it is foremost mandatory to know the power supply area in which the generated power will be transmitted. Furthermore, the power demand itself and its growth mainly depend on the growth of the population, the increase of the per capita consumption itself and the growth of the economic strength in the area. The per capita consumption usually increases with an increase in the economic strength which highly depends on the available electrical energy.

2.5.2 Basis of Load Demand Forecast

Reports of PC-I "Establishment of Regional Grids in Gilgit-Baltistan Phase- I & II" have been used to carry out the Load Forecast as it is recently prepared by the Water and Power (Gilgit-Baltistan). In this report, load demand forecast has been made using WAPDA's methodology (trend analysis) which takes into consideration the annual electricity consumption of domestic, commercial, craft and other users assessed and the historical growth rate for each is calculated on the of available data collected during the survey or the information received from census authorities.

The historical growth rate of each category is further adjusted for forecast keeping in view the prevailing conditions, load factor, increase in standard of living etc. The adjusted growth rates are then adopted for each category and accordingly load demand forecast is worked out.

During survey, the number of consumers, their connected load, their annual energy consumption, population of each area etc. is obtained for the initial years. The demand for the initial year is calculated, and further projected at the adjusted growth rates. Requirement of power energy may be carried out for a period of ten, twenty or thirty years in demand Forecast.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The period will be covered from 2021 to 2050 (30 years). The reason to extend the plan upto 2050 is to bout with the National Power IGCEP Plan 2047, prepared by the NTDCL. These demand estimates are made for domestic, commercial, crafts, agriculture, industries, public services and lights separately for various load centres identified in ten districts of Gilgit – Baltistan.

As autonomous load is essentially the demand of power of the population in a locality. Thus the rate of population growth is the main determining factor for future load development. It is therefore, essential to give the basis of population growth rate for determining annual power demand as shown In Table 2-11.

2.5.3 Parameters of Load Demand Forecast

To develop parameters for prospective power consumption by different types of consumers of different locations/villages of Gilgit-Baltistan, the related results of similar area of other provinces of Pakistan have been studied and used as basic reference for the development of parameters etc. However, the effects of local climate, terrain and financial states of the public have also been considered while designing basic parameters etc.

Based on load demand and energy consumption survey carried out in the sample urban and rural localities, Load demand parameters have been developed for rural and urban localities. Considerable accuracies in proportionate to increase/decrease with the population census have been recorded.

2.5.4 Parameters Categorization

The load demand forecast parameters adopted for rural and urban localities of different districts of Gilgit-Baltistan are given in the following table.

Table 2-12 Load demand parameters Rural Consumers

Sr. No	Type of consumers	Load (KW)
1	Domestic	2
2	Commercial	3
3	Community	5
4	Small industry	12
5	Pump water supply	15
6	Pump irrigation	7.50
7	Street lights	3

Table 2-13 Load Demand parameters Urban Consumers

Sr. No	Type of Consumers	Load (KW)			
		3-5 Marla	7-10 Marla	1-Kanal	2-Kanal
1	Domestic	3	8	12	20
2	Commercial	10	15	20	25
3	Community	10	15	26	30
4	Small Industry	10	15	30	60
5	Pump water supply	-	-	-	40
6	Pump irrigation	-	-	-	25
7	Street lights	-	-	-	0.2

2.5.5 Load Forecasting Results

Based on above various power demand/ load forecast has been estimated in terms of maximum power which generally occurs in January, required for the present connected consumers and the deprived villages. According to the assessment of the existing load position

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

in the area optimistic scenario is not far from realistic demand assessment and could be considered as the likely power demand/ load forecast of the regions in Gilgit-Baltistan. The load forecast up to 2050 is tabulated as under:

Table 2-14 Load Demand Forecast (MW) Gilgit-Baltistan upto 2050

2.5.6 Estimated Power and Energy of Attabad Lake Hydropower Project

Attabad Hydropower Project will be constructed on Hunza River and KKH is the only way to approach the project. This route has prominence due to China-Pak Economic Corridor (CPEC), which started in Pakistan from the Khunjerab Pass. The main focus in Market survey/ load forecast is being kept on the Hunza region as power will be transmitted to Sost (Upper Hunza) and Aliabad (Central Hunza), further interconnected to the regional grid of Gilgit-Baltistan from the proposed switchyard of Aliabad and also available to supply the power to Lower Hunza and Nagar Valley as 132/66/11 Grid proposed in Sikandarabad Headquarter of Tehsil Nagar-2, Nomal and Gilgit city.

The power and energy have been estimated based on 10-day flows for all years from 1966 to 2015. For 10-Daily Power Curves, the optimum installed capacity would be 54 MW with environmental flow of 3 m^3/s having mean annual energy of 373.69 GWh. The plant factor will be taken as 79 %.

The calculated annual energy, for years 1998 (average year), 2011 (wet year) and 1996 (dry year), is 375.75, 449.49 and 333.87 GWh respectively. The energy calculated based on 10 daily flows for 50 year ranges between 333.87 GWh to 449.49 GWh. A mean value of 373.69 GWh has been taken as mean annual energy. The 10 daily power and energy for average, wet and dry years are presented below.

As in average year, the installed power of 54 MW would be available for 24 hours from May to October. Peaking power (4 hours) will be available throughout the year, however, off-peak power (20 hours) will vary from 14 MW to 54 MW and will remain full from May to October. When flow reduces due to winter in November, the power generation would also reduce, however, enough flows remain available to run one turbine unit during lowest flow period as indicated in Figure 2-34.

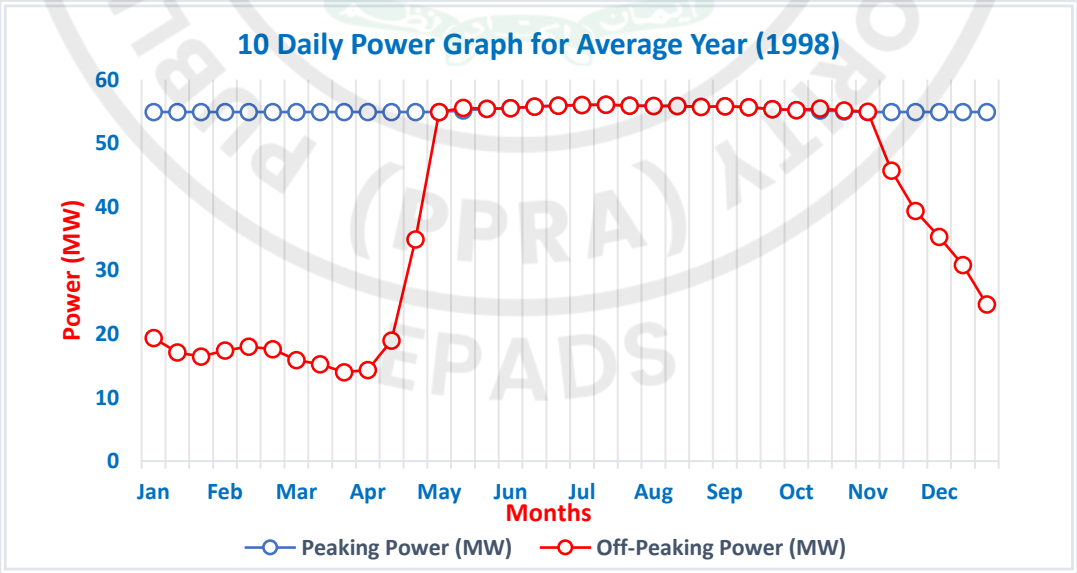

Figure 2-34 10-Daily Power Graph for Average Year (1998)

In wet year, installed power of 54 MW would be available from May to mid-December. Power may reach to full capacity during high flows of wet year even in February and March. In low flow period, the minimum power is estimated to remain at 20 MW as indicated in Figure 2-35.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

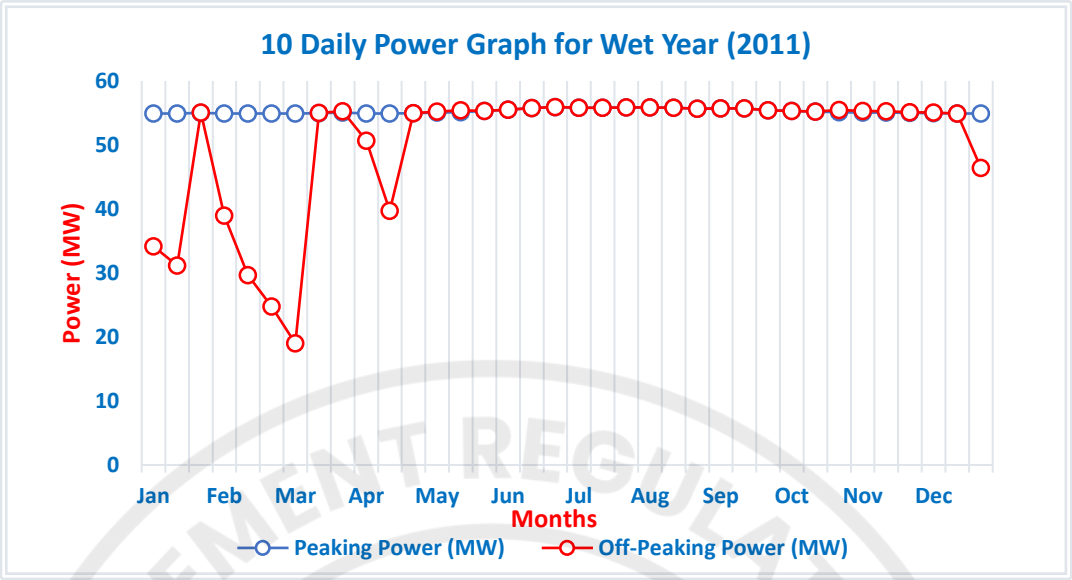

Figure 2-35 10-Daily Power Graph for Wet Year (2011)

In dry year, installed power of 54 MW will be available from June to mid-October and reduces as low as 9 MW when minimum flows are available. For dry year 1996, the power variation over the year is indicated in Figure 2-36.

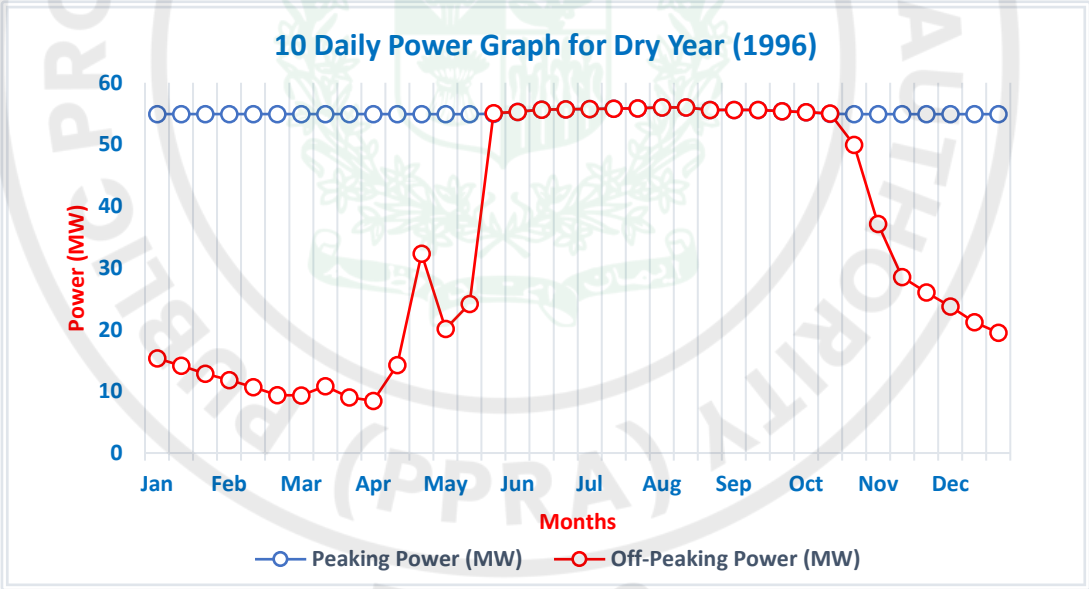

Figure 2-36 10-Daily Power Graph for Dry Year (1996)

The mean annual energy for the recorded period from 1966 to 2015 has been estimated and it is graphically presented in Figure 2.37. The graph indicates that the estimated annual energy over a period of 50 years does not vary much and remain quite consistent with little variation. It varies from 333.87 GWh to 449.49 GWh with mean value as 373.69 GWh. The plant factor for 54 MW power plant would be 79%. The low variation in mean annual energy and high plant factor indicate the reliability of hydropower from the lake.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

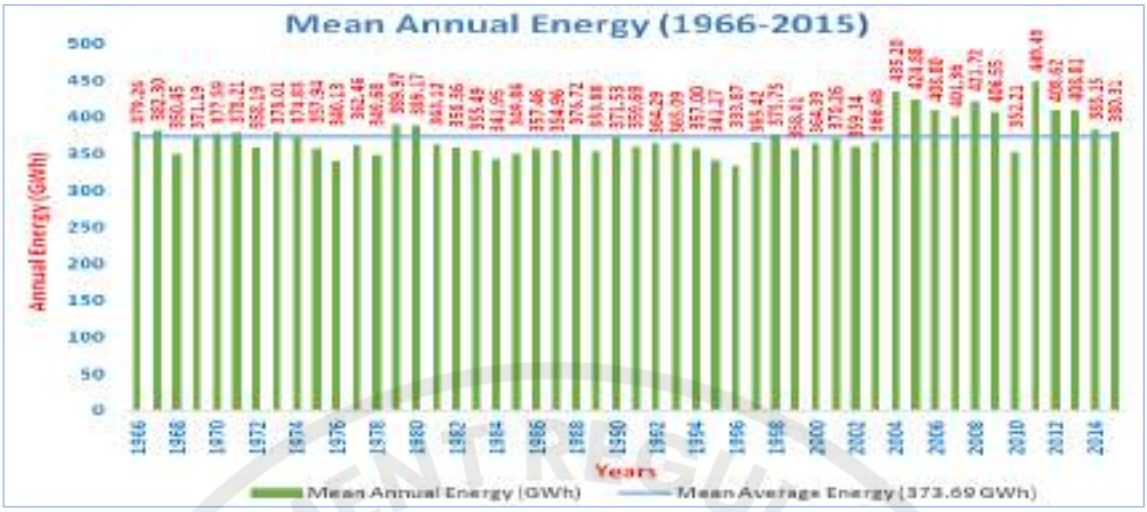

Figure 2-37 Mean Annual Energy from (1996 to 2015)

A comparison has also been plotted between monthly energy generations for Wet, Average and Dry years. Mean Annual Energy Curves indicate the trend of variations of monthly energies in GWh. The graph is shown at Figure 2.38.

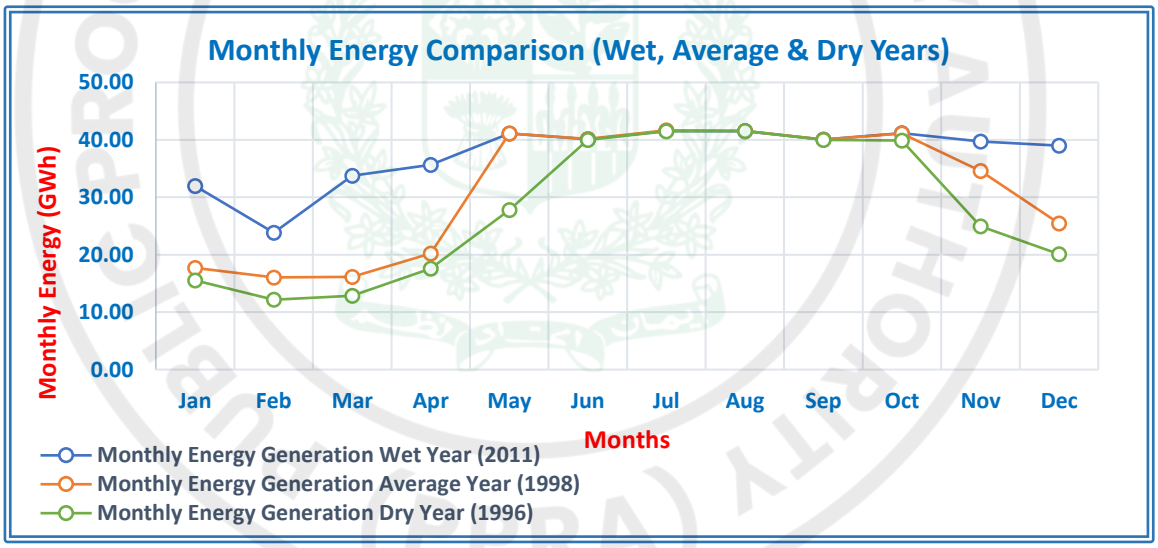

Figure 2-38 Monthly Energy Comparison (Wet, Average & Dry Years)

3 TOPOGRAPHIC AND HYDROGRAPHIC SURVEY

3.1 GENERAL

Topographic survey is imperative for planning and design of engineering projects. In order to prepare the Feasibility Design of a project, the site topography obtained through survey and mapping should not only accurate but also readily available in an acceptable format for use in the next stages of the project. For this Project, initially Survey of Pakistan Maps / GT sheets on 1:250,000 & 1:50,000 scale for the Project Area have been utilized for obtaining topographic information for preliminary studies and Project Layout. This information has been used to carry out field surveys. Moreover, these GT sheets have been used to assess the catchment area of the Project for hydrological assessment.

3.2 TOPOGRAPHY OF THE HUNZA RIVER

Hunza River, a left bank and major tributary of Gilgit River in Gilgit Baltistan (GB), originates from the confluence of the two rivers i.e. Khunjerab River and Ghujerab River, near a tunnel about 7 km upstream of an area named Shachkatr. The Khunjerab River begins in the snow-clad mountains and glaciers in the north and south of Khunjerab Pass. The river flows to the west then turns southward. It ends when it flows into the Hunza River. The Ghujerab River starts from small glaciers and snow-topped mountains of the Ghujerab Range, and flows to the west and later joins Hunza River.

Passing through the whole Gojal Valley, Hunza River falls into Attabad Lake near Shishkat Village and again emerges from it near Attabad Village. From there, Hunza River flows through main Hunza Valley and later on discharges into the Gilgit River at Danyore Village near Karakuram International University (KIU).

The catchment area of Hunza River upstream of the Project Site is about 8,900 km² which mostly consists of glaciers and snow deposits accumulated in the mountainous region usually during winter. Hunza River cuts through the Karakoram Range and flows approx. 250 km with an average slope of 0.90% from north to south before it merges into the Gilgit River. Many large size glaciers like Batura, Passu, Ghulkin, Gulmit, Bliglong, Minapin, Hasanabad and Muchlobel Glaciers drain in Hunza River. The water from main streams including Chaprot, Hasanabad and Molma Nullahs from large as well as small valleys also drains into the Hunza River. The discharge of Hunza River has its peak in months from May to September due to melting of snow/glaciers due to rise in temperature.

The main tributaries of Hunza River include Kilik, Chapurson, Shimshal, Hispar, Bar Budalas and Naltar River. Kilik River begins in the slopes of the mountains between Mintaka and the Kilik pass and flows to the south east and ends when it empties into the Hunza River. Chapursan River begins in the area of the Chilanji Pass and the slopes of Kampiri Diwar peak. It flows to the east and joins Hunza River near Khudabad. Shimshal River begins in the Shimshal Pass from Virjirab, Yezghil and Khurdopen Glaciers. It flows to the west and after reaching near Passu it joins the Hunza River. The Hispar River forms from the melt water of the Hispar Glacier flows northwest, passing through Hispar, Hopar and Nagar villages until the confluence with the Hunza River in the Hunza Valley. Naltar River begins from the Shani Glaciers and flows along Naltar Valley in south east direction to join Hunza River.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Hunza River is the main river of the Hunza Valley, which is a very scattered settlement with meager population, bordering with Khyber Pakhtunkhwa to the west and the Xinjiang Region of China to the north-east. It is surrounded by high peaks namely Rakhaposhi, Hunza, Darmyani peak, Ghenta Sar, Ultar Sar, Bojahagur Duanasir and Lady Finger peak. Karakoram Highway (KKH) (N-35) runs along the Hunza Valley, switching to the Khunjerab Pass at the border with China Xinjiang. The valley consists of three regions i.e. Upper Hunza, Central Hunza and Lower Hunza. The Upper Hunza (Gojal) is beautiful valley starts from Attabad Lake and extends to Misgar, Shimshal and Chapurson (border areas). Gulmit Village is capital city of upper Hunza and Sost is important village for commercial purposes. KKH runs from this region of Hunza and exit to neighboring country China, at Khunjareb Pass and from Chapurson Wakhan Corridor. Central Hunza is most populous Region of Hunza starts from village Murtazabad and ends at Attabad. Lower Hunza starts from a village Khizirabad and ends at Nasirabad. The Nasirabad's location on KKH makes it as a centre village of Lower Hunza. KKH enter into this Region on the first bridge of Hunza, at Nasirabad from Nagar Valley.

3.3 ATTABAD LAKE

In January, 2010, Attabad Lake was formed due to massive landslide near Attabad Village. The landslide disaster resulted in blockage of flow of Hunza River, complete submergence of Ainabad & Lower Shishkat Villages and partial flooding of Gulmit Village, displacement of population and submergence of about 19 km section of Karakoram Highway (KKH) along left bank of Hunza River. As the Hunza River backed up, the lake extended 22 km upstream and rose to a depth of 120 m. An open cut spillway 415 m long, 60 m wide and 54 m deep was constructed on the landslide mass by Frontier Works Organization (FWO) to pass flow of Hunza River over the spillway and to avoid further backing up of Hunza River in upstream Valley.

The Lake is surrounded with towering mountains on both sides and is now one of the main attractions in Hunza valley that leads to the tourism. KKH passes through 05 road tunnels (07 km long) on its left bank. The length of Attabad Lake varies from 9 km to 12 km depending upon the variation of summer and winter flows of Hunza River.

Figure 3-1: A view of Attabad Lake

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.4 PROJECT AREA

ALHPP is proposed on Attabad Lake along N-35 (KKH) in Hunza Valley. The Project Area generally comprises of loose material and fragmented terrain along the right bank of Hunza River whereas left bank is stable. The weir site has been proposed at existing spillway of Attabad Lake. The powerhouse site is about 2.5 km downstream of the Weir site, along the left bank of Hunza River.

3.5 ACCESSIBILITY

3.5.1 Roads Network

The Project is accessible from main cities of Pakistan, primarily Islamabad and Gilgit along the existing N-35 (KKH). KKH starts at Hassanabdal and passes through KPK and the GB and terminates at Khunjerab Pass in the Karakoram Range on the Pakistan – China border:

The route through KKH can also be alternatively accessed via Motorways from Islamabad to Burhan Interchange near Hassanabdal (M-1 Islamabad-Peshawar Motorway – 44 km) and from Burhan Interchange to Thakot (M-15 Hazara Motorway – 180 km). From there, the access onward to Gilgit and Hunza continues as a part of Karakuram Highway (Thakot to Gilgit – 390 km; Gilgit to Attabad Lake/Hunza along Hunza River – 120 km).

There is another route from Islamabad to Gilgit and Hunza via Babusar Pass, through National Highway (N-15). This route is although shortest than KKH through Besham, to reach upto Chilas but it usually remains closed for six months in a year due to heavy snowfall during the winter season. The road distances from various places within Project Area and other parts of country are tabulated in **Table 3-1:**

Distances of Important Places from Project Area

Sr. No.	Project Vicinity		Outside Project Area	
	Place	Distance (km)	Place	Distance (km)
1	Passu	36	Khunjerab	150
2	Hussaini	25	Gilgit	120
3	Gulmit	18	Chilas	240
4	Shishkat	15	Babusar Pass	275
5	Sarat	03	Besham	450
6	Salmanabad	3.5	Islamabad	735
7	Karimabad	15	Lahore	1,100
8	Aliabad	20	Karachi	2,300

3.5.2 Airport and Air Link

Gilgit Airport is the nearest facility to the Project Area. The Gilgit Airport is about 120 km from the Project Site. Domestic flights from Islamabad airport are schedule for Gilgit on daily basis but viability of the flight depends upon the weather conditions persisting there. Recently, flights from Lahore and Karachi are also operational to Gilgit Airport.

3.5.3 Project Layout

The weir site has been proposed at existing spillway of Attabad Lake alongwith sediment flushing structure. Water will be diverted to powerhouse through power intake, low pressure

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

headrace tunnel, surge tank and penstock on the left bank. The coordinates of weir & powerhouse sites are listed below:

Site	Easting (m)	Northing (m)
Weir	484036.834	4018143.837
Powerhouse	481645.920	4017963.719

The proposed overflow weir / ungated spillway is 60 m wide overflow and a sediment flushing channel / undersluice 19 m wide on its left site. The powerhouse site is about 2.5 km downstream of the proposed overflow weir / ungated spillway along the left bank of Hunza River.

A design discharge of 60 m^3/s will be diverted towards the powerhouse through intake left bank waterway located upstream of overflow weir / ungated spillway. A 2.32 km long low pressure headrace tunnel having a diameter of 5.5 m would run along the left bank leading to a 10 m wide and 45 m high surge tank. From there, a 470 m long embedded steel penstock with 3.6 m diameter would be laid over the left bank slopes leading down to the surface powerhouse to generate 54 MW with 03 Francis turbines. From powerhouse, a 20 m long tailrace channel leading from each generation unit will discharge water back into the Hunza River.

The **Photographs 3.2, 3.3 & 3.4** presents a view of existing spillway of Attabad Lake, proposed intake, surge tank & powerhouse areas.

3.6 TOPOGRAPHIC SURVEY

3.6.1 Available Topographic Information

Topographic information of the Project Area available at the beginning of the Study for the ALHPP comprised the following Survey of Pakistan (SoP) Maps:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

GT Sheet 42-L with scale 1:250,000.

GT Sheets 42-L/11 and 42-L/15 with scale 1:50,000 (**Photo 3.5**).

These maps have been used in the preliminary project assessments e.g. to develop the general project layout to estimate the catchment area, study of topographical and geological features etc.

In addition to the study of Survey of Pakistan Maps, the Satellite based survey data has also been utilized to get first-hand information regarding the topography and contours of the Project Area. Additionally, a comprehensive terrestrial survey program was setup and executed by Survey Division Peshawar, HPO WAPDA equipped with state of the art equipment and experienced staff. The corresponding activities have been carried out in accordance with the requirements of the scope of work.

This section describes the topography of the Project Area, applied methodology, description of control points & benchmarks carried out during the Feasibility Study and the results of the topographic survey.

3.6.2 Scope of Work

For the development of an adequate Topographical Maps for ALHPP, depicting the existing features both natural and man-made and specific land areas with ground levels, the following major activities have been carried out:

- Setup a Project trigonometric network with a system of Benchmarks.
- Terrestrial survey of the area of Project components about 400 hectares at scale 1:1000 with contour interval of 2 m, covering 4 km downstream of weir site along Hunza River.
- Longitudinal profile of Hunza River, 4 km downstream from weir site.
- Terrestrial survey of valley cross sections along Hunza River, 4 km downstream of weir site at an interval of 200 m, covering the main river course and valley slopes upto 200 m on either side.
- Terrestrial survey of borehole locations.
- Satellite based survey of the Project Area

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

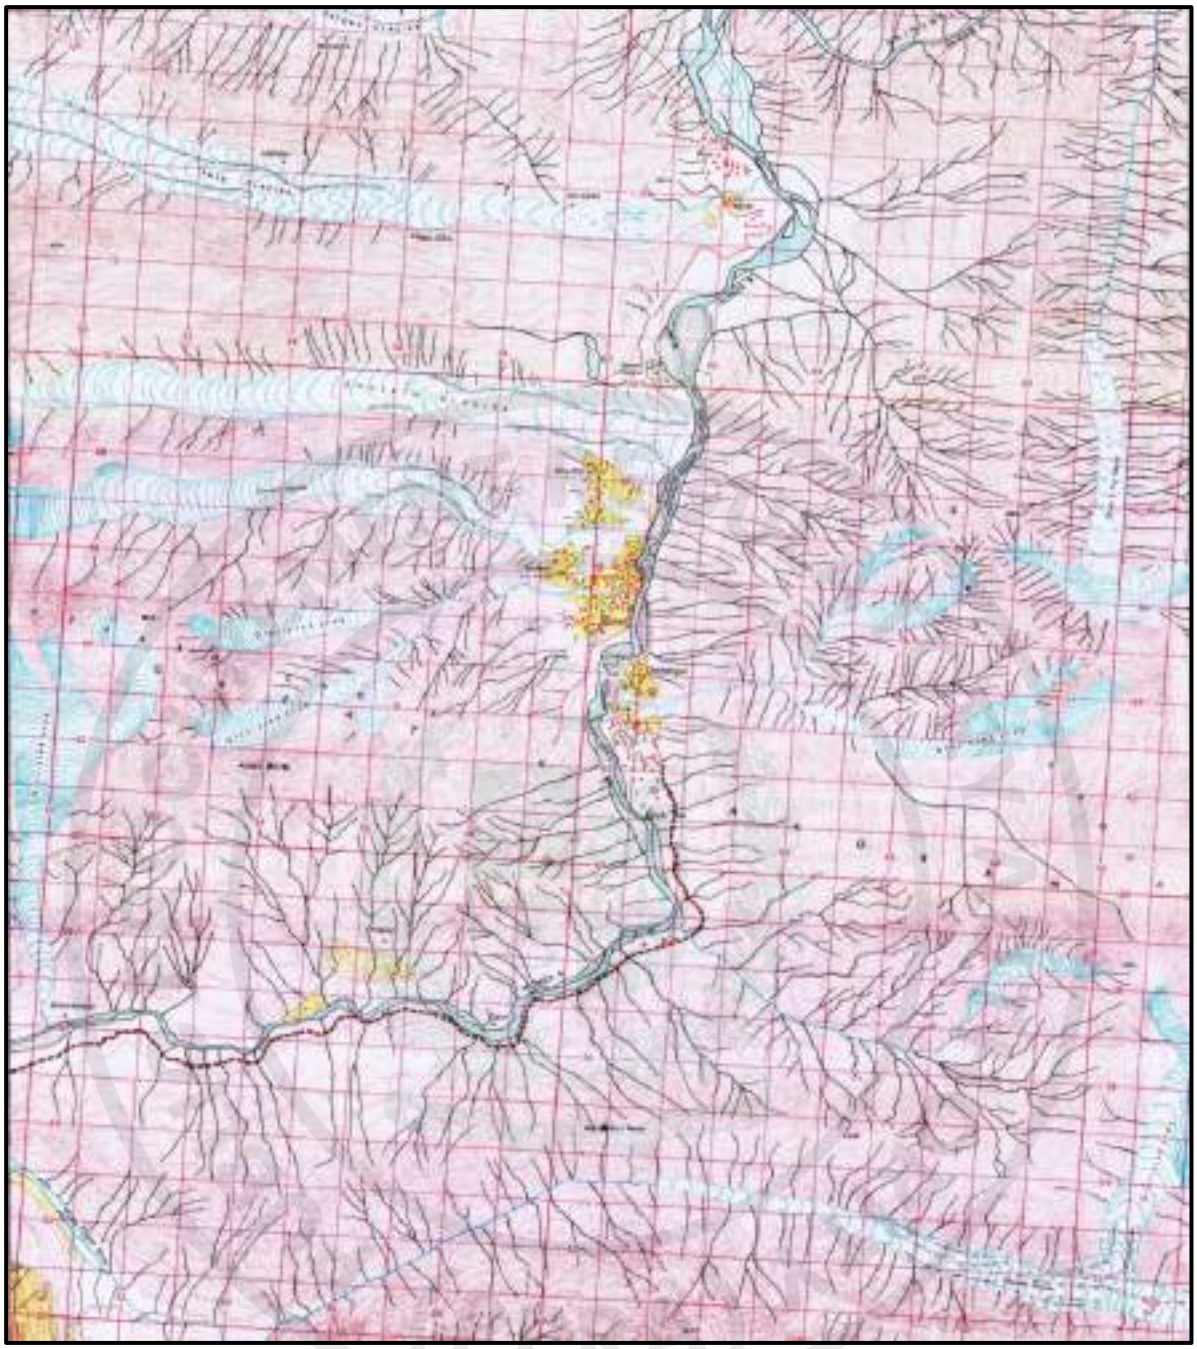

Figure 3-5 Map Section of Survey of Pakistan Sheet 42-L/15

3.6.3 Survey Standards and Requirements

All the survey work for the Feasibility Study of ALHPP has been conducted in accordance with the minimum Performance Standards and in line with the Survey Standards of Survey of Pakistan (SoP) in terms of “Accuracy and Precision”. The Survey Standards and Pre-requisites to be observed during the survey work are as under:

3.6.3.1 General

The horizontal and vertical geodetic system to be introduced for the ALHPP based on Survey of Pakistan. Installed permanent stations, control points; traverse points etc. referred to those co-ordinates and elevations. To avoid unnecessary, long traverse lines control points have been established and determined as close as possible to the individual survey sites. Control points

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

referred directly to control points of the Survey of Pakistan and determined by traverses or triangulation or any combination of them.

Traverse lines started and close at the nearest control points of the Survey of Pakistan at pre-installed and surveyed control stations. Permanently marked traverse points at interval of about 1 km. However, as many as possible fixed points shall be permanently marked out in the Project Area for later reference. All fixed points-control stations, permanent traverse points, benchmarks be marked by cast in bolt or steel pin for centering and elevation reference. The station with their designation be made clearly visible in the filed by enamel paint for easy identification.

3.6.3.2 Triangulation

In the chosen system all horizontal and vertical angles and all inclined distances have to be observed directly. The horizontal and vertical angles must be observed in three complete rounds. The mean of the rounds not exceed 2". Inclined distances must be measured directly, in both fore-sighting and back sighting directions.

Total stations with a standard deviation for angle measurement of +1" and for distance measurement of +2mm+2ppm has been employed. For each point, station compensation has been carried out. The closing error of triangles with station compensated angles has not exceeded 5". The inclined measured distances shall be reduced to the horizontal by the reciprocal-calculation method taking into consideration refraction and earth curvature. The same has to be employed for trigonometrically calculated differences of height.

3.6.3.3 Control Points Determination

For the determination of control points by traverses total station with a standards deviation for angle measurement for +1" and for distance measurement of +2mm+2ppm shall be employed. The horizontal angles shall be observed in two complete rounds with a mean of not exceeding 8". Distance shall be measured in fore-and back-sight directions.

All traverses shall be connected and closed to co-ordinate points of the Survey of Pakistan (SOP). To minimize set-up errors, the forced centering method has been applied. The closing errors shall be distributed according to common survey standards. For closed-traverse lines the allowable error shall be:

- Horizontal-angle closing $\pm 2" \sqrt{N}$
- Where "N" is the number of traverse stations distance closing $\pm 0.05\ m \sqrt{Dkmt}$
- Where "D" is the total distance of traverse line (in km).

3.6.3.4 Technimetrics Traverses

Technimetrics traverses necessary for the connection of the topographic area and section surveys at the powerhouse site has been carried out by total stations. All tachometric traverses have been closed to prior coordinated stations and their closing errors distributed.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The closing errors shall not be larger than:

Horizontal-angle closing	$\pm$1" $\sqrt{N}$
Where "N" is the number of traverse stations.	
Distance	$\pm$ 1.0 m $\sqrt{Dkm}$
Where "D" is the total distance of the line (in km)	
Height	$\pm$ 0.2 m $\sqrt{Dkm}$
Where "D" is the total distance of the line (in km)	

3.6.3.5 Precise Leveling

For precise leveling, SOP level with plan-parallel plate, with at least a count of 0.1 mm, or equivalent digital leveling instruments has been employed, using invar-leveling staffs. All leveling loops have been leveled in fore and back directions. Special care has to be taken that the distances of back and fore-sights are equal and not longer than 30 m. All back and fore-sight distances have to be recorded. No intermediate readings have been taken.

Pf error has to be allowable error	$\pm$1.0 mm $\sqrt{Dkm}$
Where "D" is the total length of the line	

The distribution made proportional to the length of the sights.

3.6.3.6 Ordinary Leveling – 3rd Order

All the lines have been surveyed in fore and back sight directions. It have been aimed that distance for back and fore sights do not differ very much. Intermediate observations to bench marks have been avoided. All level loops have been started, connected and compensated to prior determined benchmarks. The accuracy for survey have been shall be:

Between fore and back-leveling	(6 $\sqrt{Dkm}$) mm
Loop between two bench marks	(2+6 $\sqrt{Dkm}$) mm

Where "D" is the total length of the line (in km)

The error distribution is to be made either proportional to the length of the sight or to the number of instrument settings.

3.7 METHODOLOGY APPLIED TO THE TOPOGRAPHIC SURVEY

For the topographic survey of ALHPP, the following two approaches have applied comprising:

- Conventional terrestrial survey used for detailed topographic maps with high accuracy.
- Satellite based survey used for overview project maps:
- Google Earth Method.
- Geographic Information System (GIS) Method.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The following surveying works have been carried out during the Feasibility Study:

Establishment of ground control points;

- Terrestrial survey works of weir and powerhouse site covering Project components including weir & sediment flushing channel, power intake, power tunnel, surge tank, penstock, powerhouse and tailrace area;
- Longitudinal profile of Hunza River;
- Terrestrial survey works of valley cross sections along Hunza River;
- Survey of locations of bore holes;
- Development of Topographic Maps at the required scales.
- Development of Digital Elevation Model (DEM) based on high resolution satellite images.

3.7.1 Reference System

In order to start the topographic field survey work, the reference grid of Survey of Pakistan (SOP) is required to be connected. However, there was no standard Benchmark (BM) established by SOP in the vicinity of Project Area and its surroundings. Due to the non-availability of the SoP BM, the reference BM has been established in the Project Area by using Differential Global Positioning System (DGPS).

The benchmarks established through DGPS have been verified with the Total Station. The terrestrial survey of the Project Area has been carried out with reference to these benchmarks to prepare topographic features of ALHPP.

3.7.2 Instruments Used

The terrestrial topographic survey has been conducted using Electronic Total Stations. The conditions of the survey instruments have been checked prior survey to ensure high accuracy of the record data. The following instruments have been used for the terrestrial survey works:

- Topcon Total Station W 0303.
- Trimble R8s GNSS.

3.7.3 DGPS Survey of Project's Reference Points

The surveying campaign commenced in the early stage of the Feasibility Study in August, 2020. Due to non-availability of the SOP BM as a reference point, it has been decided to use the DGPS-Receiver called Trimble R8s to establish reference points at Project Site. 03 locations have been identified, making triangulations.

The starting point established over a pre-constructed BM along old Karakoram highway, 190 m upstream of SCOM office located near Tunnel-1 inlet. This BM has been named as BM-1 and the receiver has set as "Base Station" at BM-1 for longer duration in static mode of observation, to collect its coordinate data.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

For the static surveying, Trimble R8s receiver is capable of giving the following accuracy:

- Horizontal 3 mm + 0.1 ppm RMS
- Vertical 3.5 mm + 0.4 ppm RMS

Keeping the “Base Station” in observation mode, another receiver “Rover” has moved to other two points i.e. BM-2 & H-35, one by one for 60 minutes to collect coordinate data. To receive the signals from satellite, it has been ensured that both the receivers have minimum obstructions like building, trees, power lines etc. The signals have received at minimum cut of angle of 15° or more. The Base Station receiver measured the errors in the GPS signals and transmitted the corrections to the Rover receiver.

The data from both the Base Station and Rover receiver then downloaded for processing and conversion from grid to ground parameters. The accuracy achieved in the DGPS survey of reference points was 50 cm. The values of these established reference points verified by the survey team using Total Station through triangulation. The coordinates and elevation of reference points BM-1 & BM-2 have further been used as Project’s Permanent Reference BM to start the survey activities in the Project Area.

Figure 3-2 Survey of Project’s Permanent Reference Benchmark BM-1

3.8 TERRESTRIAL TOPOGRAPHIC SURVEY OF PROJECT AREA

During the survey campaign, the survey of Project Area covering all the Project components, Valley Cross-Sections and Longitudinal Profile along Hunza River has been conducted as specified in the scope of work, to provide reliable data for the study of Project Layout.

The terrestrial survey work has been carried out by two experienced survey teams of Survey Division Peshawar, WAPDA. In the course of Feasibility Study, a comprehensive terrestrial survey has been conducted to achieve topographic information to the required level. One of the

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

major objectives is the elaboration of detailed topographic maps at scale 1: 1,000 with contour interval of 2 m of the area of the project structures as specified in the scope of work.

The terrestrial survey works carried out comprise weir and powerhouse site, covering the project components:

- Overflow Weir & Sediment Flushing Channel.
- Power Intake.
- Low Pressure Headrace Tunnel.
- Surge Tank.
- Penstock.
- Powerhouse.
- Tailrace Channel.

The terrestrial survey of Project Area has been completed in September, 2020. The 02 number concrete monuments BM-1 & BM-2 form the basis for a new triangulation system. All the terrestrial surveyed areas tied into the Project's Permanent Reference Benchmarks i.e. BM-1 & BM-2 near weir and powerhouse site.

Figure 3-3 Terrestrial Topographic Survey in progress

3.8.1 Horizontal Control

The horizontal control has been done through a combination of triangulation and traversing method supported by the use of reference points established through DGPS. All the survey

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

work conducted with digital display infrared beam Total Station. The triangulation network consists of well balance quadrilaterals or center point polygons and also well balance triangles.

The traversing has been in the closed loop form. All traversing lines measured in two directions (forward and backward) and mean value has been used. The linear measurement units used in the survey work and mapping work are metric and the angular measurement in degree, minutes and seconds of arc.

3.8.2 Vertical Control

The Reference Datum i.e. the mean sea level established by SOP was not available in the vicinity of Project Area; therefore, the vertical control datum of Project's Permanent Reference Benchmark BM-1 has been used as the reference datum and utilized in survey of the Project Area.

3.8.3 Traverse Survey

Before carrying out the topographic survey, a traversing network for the project was prepared. It included a plan of the temporary benchmarks / control points network across the project. The traverse survey started from reference points established through DGPS i.e. BM-1 & BM-2. The accuracy of horizontal control has been achieved with traversing using total station. With traversing, sixty eight (68) traverse stations / control points have been established by the survey team in the entire area of interest to acquire the field survey data in digital format.

The traverse stations / control points have been established on the available rocks and existing drainage structures such as culverts in the project area by marking with engraved circle or triangle and a nail driven or engraved dot at the center of either mark. All the traverse stations / control points were properly labeled with red paint.

Survey Division Peshawar, WAPDA also conducted closed loop survey which connects the traverse between the control points with the permanent benchmarks used for the survey works for the ALHPP.

Control network diagram is presented in **Figure 3.8** and the list of traverse stations / control points is given in **Table 3-1**.

3.8.4 Survey of Weir and Powerhouse Site

The terrestrial survey at the Weir and Powerhouse site was performed based on a temporary benchmarks / control points network which were tied to the two reference points i.e. Project's Permanent Reference Benchmarks BM-1 & BM-2, located about 2.8 km & 2.1 km downstream of the Weir site respectively along the old Karakoram highway.

The survey works performed at Weir site covers an area of overflow weir and sediment flushing section, power intake and headrace tunnel area. The survey works performed at Powerhouse site covers an area of powerhouse itself, surge tank, penstock and tailrace channel. The survey of Weir and Powerhouse site covers part of valley slopes on left and right bank of the Hunza River.

3.8.5 Survey of Valley Cross Sections and Longitudinal Profiles

During the survey campaign, the Survey Division Peshawar, HPO, WAPDA conducted a detailed terrestrial topographic survey of valley cross sections and longitudinal profile along Hunza River. The valley cross sections covers upto 4 km downstream Hunza River reach from the weir axis. The valley cross-sections taken at an interval of 200 m. The surveyed data of each cross-section includes left and right valley slopes down to the water level of the Hunza River. The topographic survey of these cross-sections have been conducted based on temporary benchmarks / control points network which have been tied to the two Project's Permanent Benchmarks i.e. BM-1 & BM-2.

The longitudinal water profile of Hunza River, 4 km downstream of weir axis has been surveyed to establish the river drop. The water levels are taken on the left bank of the river.

3.8.6 Survey of Locations of Geotechnical Investigations

As part of the geotechnical field investigation program of 06 boreholes core drilling and 08 test pits have been carried out for geological investigation. The location of the boreholes and test pits has been based on temporary benchmarks / control points network tied to the two Project's Permanent Benchmarks i.e. BM-1 & BM-2. The borehole and test pits locations have been marked at major project components prior to start of drilling work.

In some cases, platforms have erected for safe installation of the drilling rig in sloped terrain. Therefore, the recorded ground level of the borehole may deviate from the elevation of natural ground upto 5m.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.9 RESULTS OF TERRESTRIAL TOPOGRAPHIC SURVEY

3.9.1 The Attabad Lake Hydropower Project's Reference System

The reference system of the ALHPP is based on Differential Global Positioning System (DGPS). The results of all terrestrial topographic surveys are tied to the reference points i.e. Project's Permanent Benchmarks established in the Project Area through DGPS.

3.9.2 Benchmarks of Attabad Lake Hydropower Project

Due to non-availability of SOP BM in the vicinity of Project Area, the DGPS based Project's Permanent Benchmarks are established in the Project Area, comprising of 02 concrete monuments (BM-1 & BM-2) covering the Project Area. The two monuments were newly constructed at carefully selected sites to meet the demands of the project.

The new constructed concrete monuments are of rectangular shape and painted in white colour with their nominations indicated in red colour at two sides**.** On top of the monument a steel bolt is incorporated into the massive concrete. This steel bolt is the reference point of the monument. For protection of the steel bolt from mechanical damage the bolt is placed in a hole of the monument some 5 cm below the top.

Table 3.2 provides detailed information alongwith the corresponding photographic images about the individual monuments of ALHPP.

Table 3-2 Permanent Benchmarks in the Project Area

Name	Easting (m)	Northing (m)	Elevation (m.a.s.l)	Description
BM-1	481492.694	4017731.980	2384.000	Along old Karakoram highway, 190 m upstream of SCOM office building located near Tunnel-1 inlet.
BM-2	482045.533	4017941.757	2360.841	697 m upstream of BM-1 along old Karakoram highway.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.9.3 Detailed Topographic Maps

The results of the survey campaigns have been processed to elaborate corresponding topographic maps of the Project Area. The contour lines have been interpolated using the survey software “Eagle Point”. Further the observed data has been digitized in the AutoCAD software. The digitization of the features has been done by creating the feature layers in the software. The different layer features have the unique colour and symbols so that they can be easily well distinguished from the other feature.

In the detailed terrestrial survey, natural and man-made structures were recorded. The main features that have been recorded in the topographic survey of the Project area are:

- Slided area at the right bank of Hunza River near weir site
- Rock outcrop at the power intake area.
- Section of Old KKH downstream of Attabad Lake.
- Access road to Sarat & Attabad village.
- Bridge over Hunza River for access to Sarat & Attabad village located some 200 m downstream of proposed powerhouse.
- Flat and boulders area at powerhouse site.
- Old Chinese Camp.
- Helipads near powerhouse area.
- Tracks, paths, road culverts, protection walls and electric poles.
- Inlet & Outlet of transportation tunnel 1.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Inlet & Outlet of transportation tunnel 2.
- SCOM Office Building near inlet of Tunnel 1.
- Alignment of nullahs on left and right bank of Hunza River.

Changes in slope such as roads along the hillside and at the edges of waterways have been surveyed in detail and defined as break lines for the interpolation of contour lines. The scale of the topographic maps is 1: 2,000 with 2 m contour intervals. Based on maps at that scale, all relevant design drawings of the project structure are prepared.

The survey output at scale 1: 2,000 topographic maps of the Project Area produced based on the terrestrial survey are presented in **Volume-2** (Drawings) in 20 sheets (A3 format). All features important for the Feasibility Design of the permanent Project components are included in the survey works.

3.9.4 Survey of Valley Cross Sections and Longitudinal Profiles

21 valley cross sections surveyed along the Hunza River at an interval of 200 m d/s of weir axis. The surveyed data of each cross-section includes left and right valley slopes (ranges from 175 m to 250 m on either side) down to the water level of the Hunza River. The **Figure 3.9** gives an overview of cross sections surveyed. The left and right end points of the cross-section are given in **Table 3.3.** The drawings of each cross section at scale 1: 2,000 are presented in **Volume-2 (Drawings)** in 10 sheets (A3 format).

The longitudinal water profile has been observed along Hunza River and is placed in **Volume-2 (Drawings)**. The longitudinal profile along Hunza River is presented in 11 sheets (A3 format) at scale 1: 1,000. The total length of longitudinal profile along Hunza River is 4.05 km and there is a drop of 142 m.

3.9.5 Survey of Locations for Geotechnical Investigations

The coordinates, elevations and locations of each borehole drilled at main weir, sediment flushing channel, headrace tunnel and powerhouse are given in Section-5 (Geological and Geotechnical Studies). The survey of locations of boreholes recorded in the early phase of the Project based on temporary benchmarks / control points which have been tied to the two Project's Permanent BM i.e. BM-1 & BM-2. The different spreads of control points have been established to locate the position of boreholes in the entire Project Area.

3.10 SATELLITE BASED SURVEY OF PROJECT AREA

The Satellite based survey is a most advanced system for such purposes where several types of Geographical and Geo-physical information about the earth are observed through Satellites. Several types and forms of data from the satellite imageries are processed, analyzed and used for the specific purposes.

3.10.1 Google Earth Method

Google Earth is a geo-browser that accesses satellite and aerial imagery and other geographic data over the internet to represent the Earth as a three-dimensional globe. It renders a 3D representation of Earth based on satellite imagery. The program maps the Earth by the superimposition of images obtained from satellite imagery, aerial photography and GIS data onto a 3D globe, allowing users to see cities and landscapes from various angles.

3.10.2 Methodology

For the preliminary working, topographic data has been collected through Google Earth Pro and relevant elevations were computed through web based applications for this purpose.

3.10.3 Geographic Data

Google Earth Pro has built in tools which gives the 3-dimensional value of any location. Using this tool numerous points have been taken in the Area of Interest (AOI). All the features e.g. river boundaries, roads, inhabitation/dwellings etc. have been demarcated on Google and saved as Keyhole Markup Language (KML) files for exporting to other software for further analysis. The google earth model of the AOI is presented in **Figure 3.10**.

3.10.4 Geographic Information System (GIS) Method

Geographic Information System (GIS) refers to Satellite based Geospatial Technology which is a tool use to acquire, store, analyze, manage, and present all types of geographical information in a variety of contexts, operations and applications. The use of Geospatial Information is becoming widely used in everyday life through Satellite Navigation and Geographical Information Systems (GIS). It is used to determine precise locations all over the globe, in any weather conditions and at any time of the day.

GIS geodetic surveying equipment for land surveyors has become smaller and easier to use being faster to use than other surveying methods. GIS technology combines database, mapping and statistical methods to integrate georeferenced data into visual displays where the relationships, patterns and trends in the data can be more easily identified.

3.10.5 Fundamental Components of GIS

Geospatial technology combines key data and visual information from multiple sources and integrates everything into databases to create intelligent maps. GIS is based on two fundamental components:

- Data (Satellite Imagery / DEM); and
- Computer software to perform calculations and analysis.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

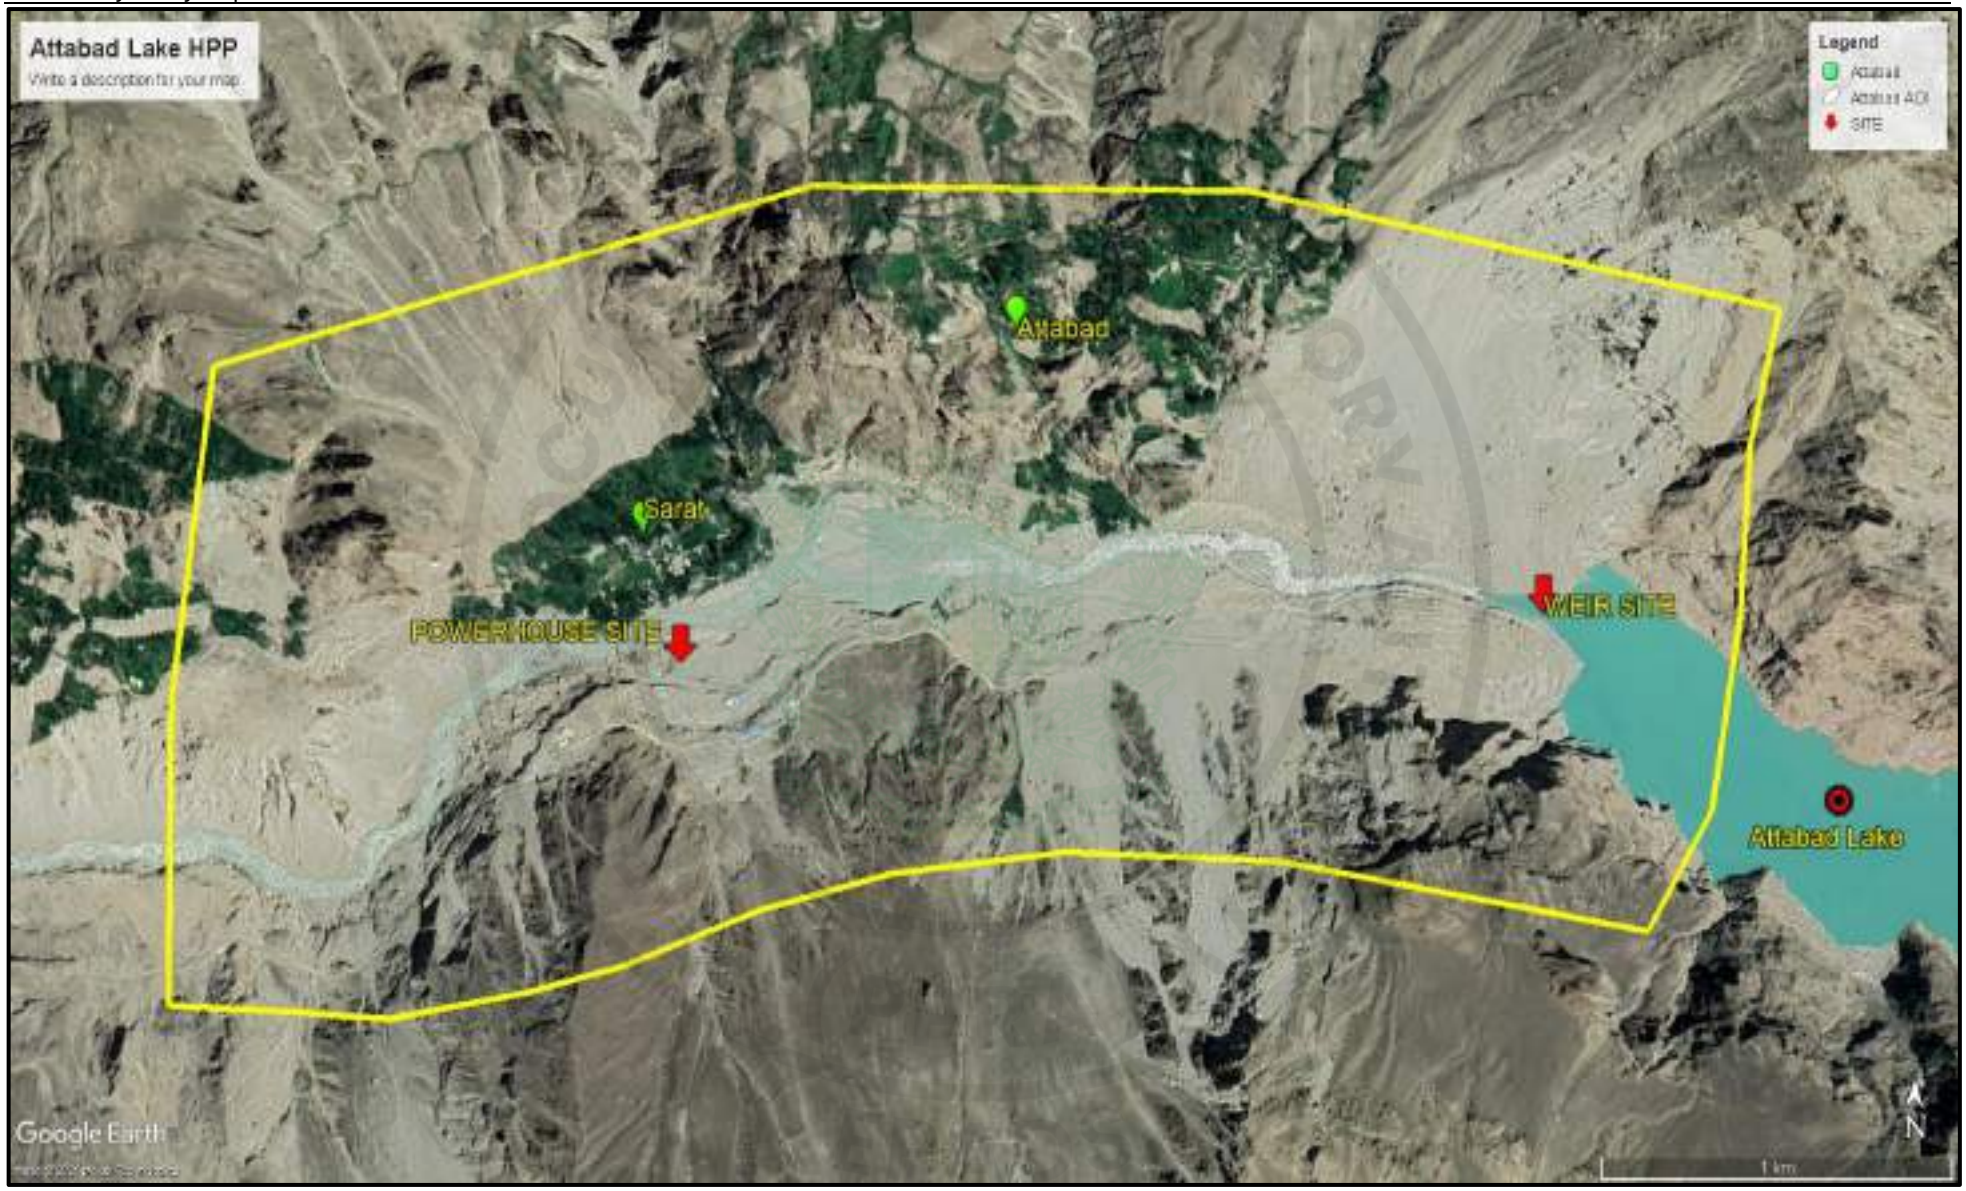

Figure 3-6 Google Earth Model

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.10.6 Satellite Imageries

A Satellite Imagery contains data hidden in each pixel, which when unlocked, can tell a lot about what is looking at. There are many analysis techniques that can be applied to multispectral imagery to extract specific features of interest. These algorithms rely on the same principles of reflectivity and absorption at various wavelengths that allow seeing certain features when visualizing them with different band combinations. The various satellite imageries are: -

- Landsat 8 Satellite Images
- Shuttle Radar Topography Mission (SRTM)
- ASTER instrument

3.10.7 Data Acquisition and Assembly

In the initial stages, it was apparent that there would be a need for a number of different data sources. This process was simplified by making a list of the data that would be required. Thereon, for the pertinent Area of Interest, various necessary High Resolution Satellite Imageries / Digital Elevation Models (DEMs) acquired through United States Geological Survey (USGS) and ESRI Portals. These were processed and analyzed using ArcGIS, AutoCAD Civil 3D and Erdas Imagine etc. The following satellite imageries were acquired and processed for geospatial analysis and processing: -

- Landsat 8 OLI TIRC C1 Level-1
- Landsat Look Images with Geographic Reference
- Landsat Look Natural Color Image
- Landsat Look Quality Image
- Landsat Look Thermal Image
- Level-1 GeoTIFF Data Product
- SRTM / SRTM 1 Arc-Second
- Google High Resolution Imageries

3.10.8 Procedure and Methodology

ArcGIS and ERDAS Imagine, top of the line software for GIS working has been used for analysis and processing of Satellite Images. ArcGIS Explorer is a GIS viewer which can work as a client for ArcGIS Server, ArcIMS, ArcWeb Services and Web Map Service (WMS). ArcGIS Online is a web application allowing sharing and search of geographic information, as well as content published by Esri, ArcGIS users, and other authoritative data providers. For introduction the steps involved are very briefly mentioned as under:

3.10.9 Coordinate Transformation

Coordinate Transformation has been carried out to transform the coordinates of the satellite image from WGS84 to projected Coordinates System of WGS 1984 UTM Zone 43N.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.10.10 Geo Referencing

The term, Geo Referencing, is commonly used in the GIS field to describe the process of associating a physical map or raster image of a map with spatial locations. It is the process of scaling, rotating, translating and deskewing the image to match a particular size and position.

PUBLIC PROCUREMENT REGULATORY AUTHORITY (PPRA) EPADS

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

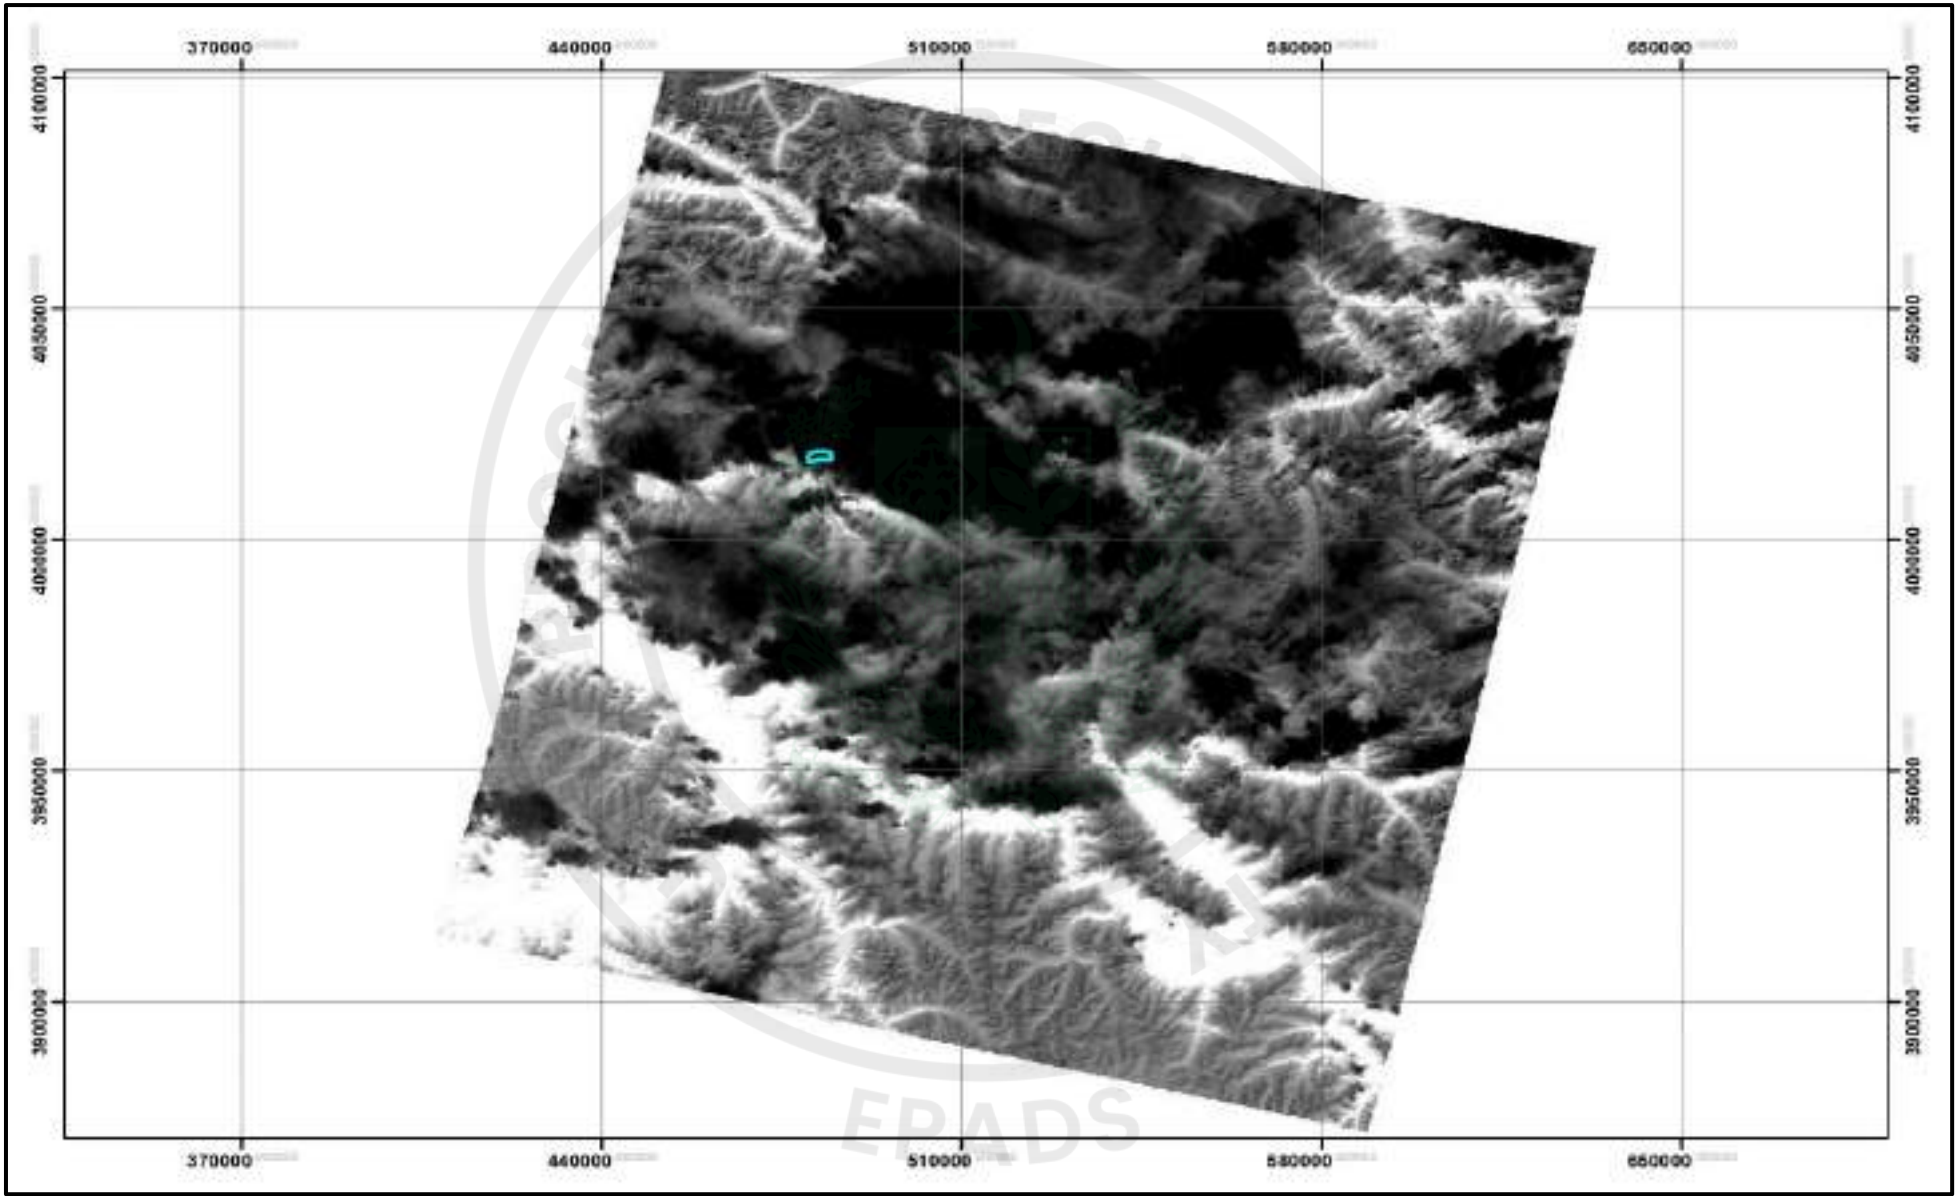

Figure 3-7 Landsat 8 Panchromatic Image

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Geo Referencing of the existing features, observed through Google Earth and with physical Site measurement, on the satellite imageries has been carried out. Proper geo-referencing done with the help of SOP Maps and exact coordinate values from the field survey.

3.10.11 Raster Mosaic

An overall Raster Mosaic from Raster Datasets covering the entire Project Area has been created. Mosaic clipping of the Raster conducted to extract the AOI.

3.10.12 Image Corrections

The applicable image corrections applied for image enhancement including the correction for Atmospheric Scattering and distortions.

3.10.13 Band Combination

As defined earlier to visualize different features, e.g. water bodies, vegetation, roads, inhabitation etc. the prescribed combinations of band were created and image classification carried out to identify features on ground.

3.10.14 Image Classification

Image classification refers to the task of extracting information classes from a multiband raster image. The resulting raster from image classification can be used to create thematic maps. Depending on the interaction between the analyst and the computer during classification, there are two types of classification: supervised and unsupervised. As a matter of fact, Object-Based (or Object-Oriented) Image Analysis Classification which is a hybrid form of classification has been used. Various features including roads, rivers and villages etc. have been digitized from panchromatic satellite images and Google Earth Pro and have been superimposed over the base map in respective layers.

3.10.15 Digital Elevation Model (DEM)

Earth observation data comes in form of 2D flat imagery. For realistic appearance, elevations are required to rectify and make those images three-dimensional. The most common digital data of the shape of the earth's surface is cell-based called Digital Elevation Model (DEM). This data is used as input to quantify the characteristics of the land surface.

A DEM is a raster representation of a continuous surface, usually referencing the surface of the earth. The accuracy of this data is determined primarily by the resolution (the distance between sample points). Other factors affecting accuracy are data type (integer or floating point) and the actual sampling of the surface when creating the original DEM. The DEM of AOI is presented in **Figure 3.12**.

3.11 HYDROGRAPHIC SURVEY

Hydrographic Survey refers to the under-water survey involving water depth measurements. In order to determine the capacity of the Attabad Lake, the hydrographic survey of the Lake has been carried out by International Sedimentation Research Institute, Pakistan (ISRIP), WAPDA during September and October, 2020.

3.11.1 Scope of Work

III. The Hydrographic Survey of Attabad Lake includes the following major activities:

IV. Cross-sections of the lake along range lines from left to right bank, at 250 m interval for first 3 km & 500 m interval for rest of the lake.

V. Computation of existing storage capacity of the lake.

VI. Development of area-capacity curve.

VII. Development of contour maps of the Lake.

VIII. Discharge Measurement at Ganish Bridge.

3.12 METHODOLOGY APPLIED TO THE HYDROGRAPHIC SURVEY

3.12.1 Instrument Used

For surveying the submerged part of the lake, an inflatable Rubber Boat and Echo Sounding equipment including a recorder, a transmitting & receiving transducer and power supply has been used. For surveying the exposed bed of the lake, Total Station and Global Positioning System (GPS) have been utilized.

3.12.2 Horizontal and Vertical Control of Cross Sections

To carry out the hydrographic survey of the lake, the horizontal and vertical control points near water edge at left bank has been established by ISRIP survey team. All the cross-sections are connected to the geodetic network used in the topographic survey.

3.12.3 Hydrographic Survey

The hydrographic survey consists of depth sounding by manual or electronic sonar equipment and position determination relative to measured depth. The reservoir depth along range lines has been determined by the sonic sounder. The accuracy of sonic sounder used in the survey is 0.5% ± 1 inch of indicated depth.

First of all the boat positioned at left bank of the lake, such that it is in line of already established range line, then sounding instrument turned on and mark has been placed on the sonic chart in order to show the starting position and depth with reference to water edge. Thereafter, the depths plotted on sonic chart with reference to left bank distance and simultaneously observed and noted the corresponding coordinate from the GPS. GPS has been used to keep the position of the boat straight as it move continuously across the range line. This process has continued until the boat touched the opposite bank and finally marked the right bank water edge.

3.12.4 Capacity Computations by TIN Method using ArcGIS

For the capacity computation of Attabad Lake, Triangular Irregular Network (TIN) method using ArcGIS have been utilized, which provides most accurate and reliable results.

Triangular Irregular Network (TIN) is preferred to represent the reservoir bed surface using the available data in more accurate manner. ArcGIS has the ability to do volumetric calculations from these surface models. TIN model is a surface representation derived from points with an X, Y co-ordinate and a Z value or surface value. TINs are a form of vector-based digital geographic data and are constructed by triangulating a set of vertices (points). The vertices are connected with a series of edges to form a network of triangles. There are different methods of interpolation to form these triangles, such as Delaunay triangulation or distance ordering. ArcGIS supports the Delaunay triangulation method. A TIN expects units to be in feet or meters, not decimal degrees. Delaunay triangulations are not valid when constructed using angular coordinates from geographic coordinate systems.

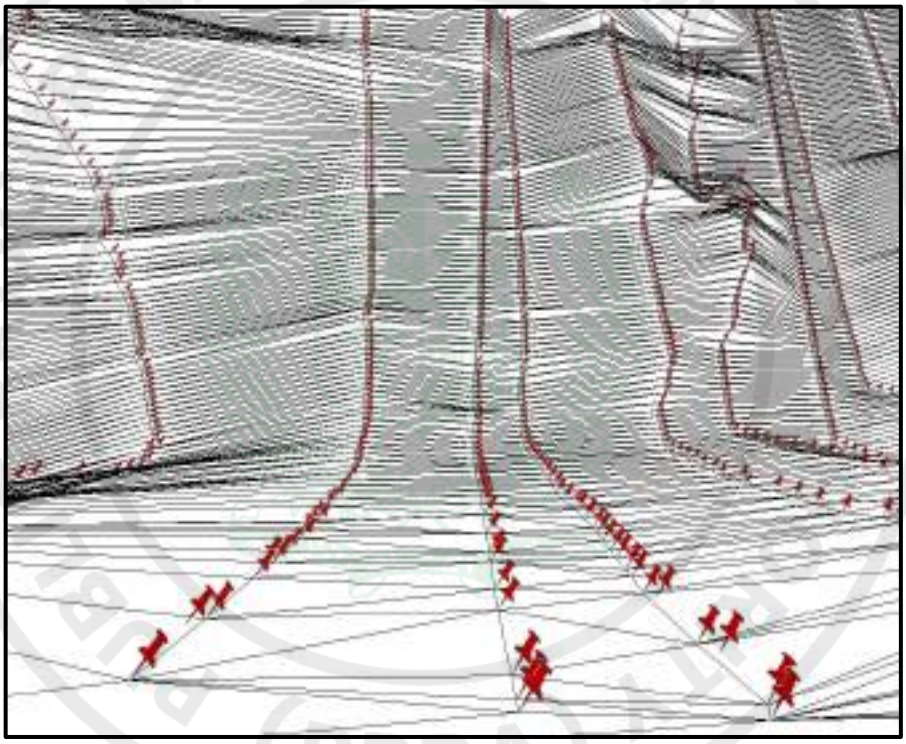

Figure 3-11 Cross-sectional Points and Triangles formed from Hydrographic Data

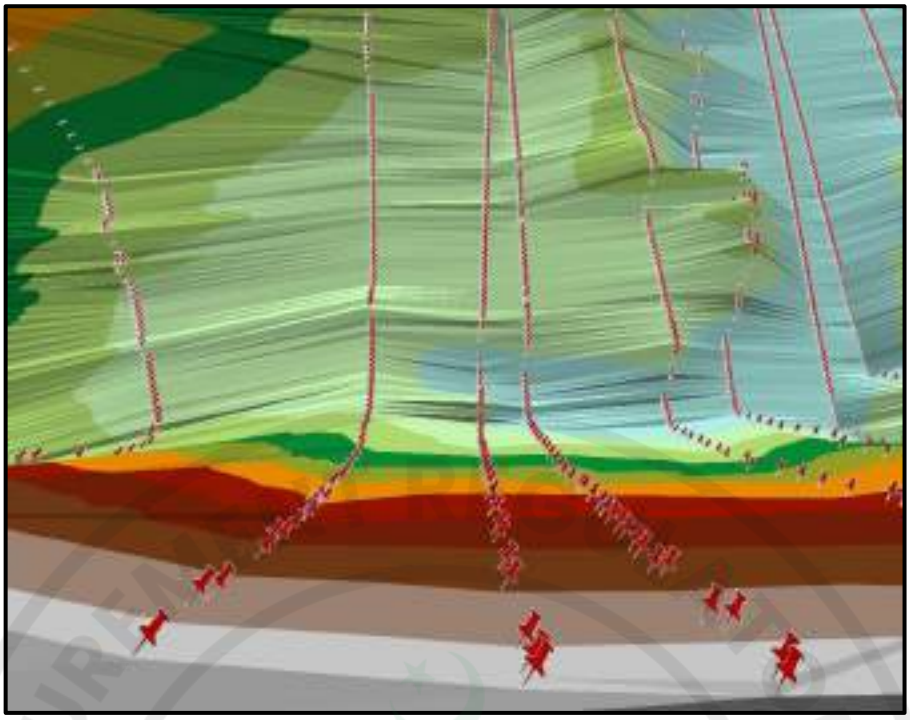
3.12.4.1 Displaying TIN Surfaces

Triangulated Irregular Networks (TINs) represent continuous surfaces such as terrain elevation or temperature gradient. The surface is represented as a set of facets formed by connecting data points at nodes to create adjacent triangles. Typically, a TIN can be displayed using color-shaded relief to depict elevation. Shaded relief simulates the sun's illumination of the earth's surface. By adding color to this, the ridges, valleys, hillsides and their respective heights can easily be seen. The Elevation map is presented in **Figure-3.16**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026



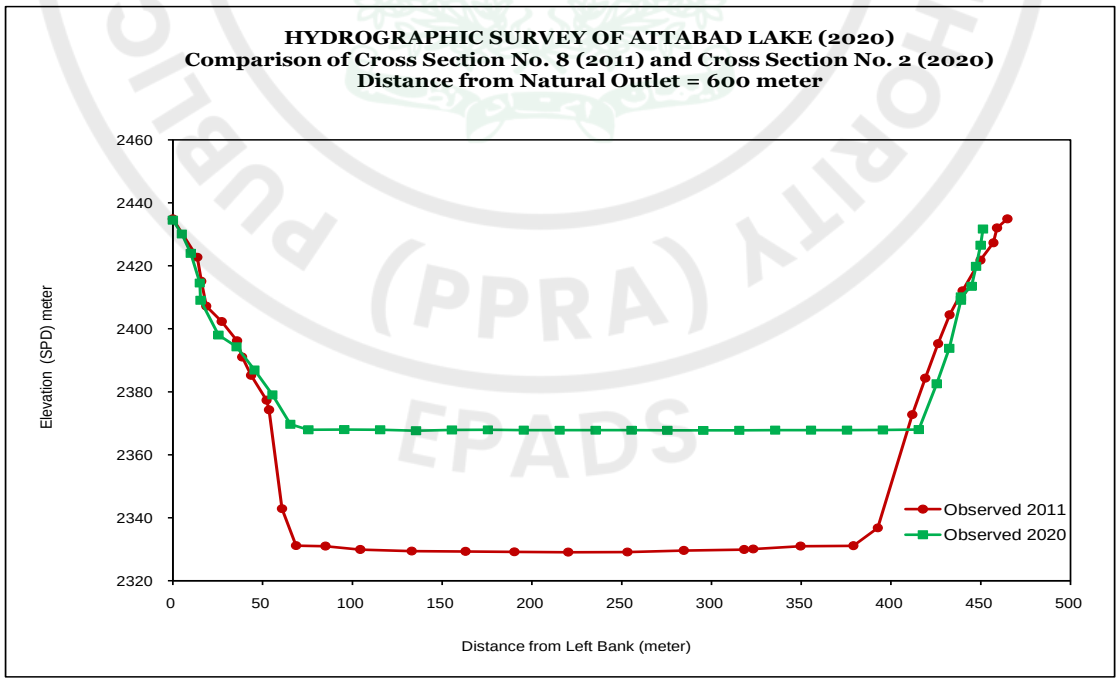


Figure 3-12 Elevation Map

3.13 RESULTS OF HYDROGRAPHIC SURVEY

The storage capacity at Maximum Conservation Level (El. 2409 masl) comes to be 99,249 Acre Feet (122.42 Mm^3). The present water surface area of lake at El. 2409 masl is 1088.7 Acres (4.41 km^2). Comparison of current data with previous survey report of year 2011 showed that on an average there is 30 to 40 m deposition in 9 years.

3.13.1 Cross Sections & Surveyed Plan of Lake

The X-Sections along 40 range lines covering a total lake length of 12,450 m have been taken. The spacing of the range lines varies between 75 m to 500 m. The width of cross-sections ranges from 245 m to 1289 m upto El. 2430 masl. The surveyed data of the observed cross-sections is

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

presented in Volume-7 Appendix-I (A). The drawings of each cross-section are presented in **Volume-2 (Drawings)** in 40 sheets (A3 format). To give an idea about the geometry of the lake area, the contour plan and elevation bands have also been developed and presented in **Volume-2 (Drawings)**.

3.13.2 Comparison of Selected Cross Sections

For comparison of depth, the 04 X-Sections at a distance of 600 m, 1,400 m, 9,720 m and 11,920 m from natural outlet (spillway) selected and superimposed with previous observed survey data of 2011. The comparison of these cross-sections is presented in **Volume-2 (Drawings)** in 04 sheets.

3.13.3 Longitudinal Bed Profile

Longitudinal bed profile have been observed, using sonic sounder. At the time of longitudinal profile observation, water surface level has also been observed to facilitate the computation of bed levels from echo sounding data. Digitized sonic profile data and mean bed levels of the cross-sections were used to prepare longitudinal profile, presented in **Volume-7 Appendix-I (C)**.

3.13.4 Thalweg Profile

The minimum bed elevation at each cross section along the length of the lake has been used to plot the Thalweg profile of lake and is presented in **Volume-7 Appendix-I (D)**.

3.13.5 Capacity and Surface Area

The capacities and surface areas have been computed from ArcGIS using Trianguled Irregular Network (TIN) Method. The capacity and surface area of the lake at different elevations has been calculated. The area-capacity data is presented in **Volume-7 Appendix-I (B)**.

3.13.6 Discharge Measurement at Ganish Bridge

The discharge observations have been taken at Ganish Bridge in the month of September and October 2020. The cross-sectional data and discharge sheets are presented in **Volume-7 Appendix-I (E)**.

3.14 QUALITY CONTROL

The topographic and hydrographic survey has been conducted by qualified and experienced team of Survey Division, Peshawar, HPO WAPDA and ISRIP respectively in accordance with the scope of work. Before the start of survey activities, the survey equipment has been calibrated to avoid any error. Apart from this, certain check measurements has also taken during the survey campaign for assuring the quality work.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4 HYDROLOGY AND SEDIMENTATION

4.1 GENERAL

Northern Areas of Pakistan is unique in its geographical configuration and layout which houses confluence of three major mountain ranges i.e. Hindukush, Karakorum and Himalayans and 5 out of 14 peaks above 8000 m.a.s.l. The Hindukush-Karakoram-Himalaya (HKKH) Region, often called “Water Towers of Asia,” provides natural reserves of fresh water in the form of snow and glaciers that sustain water availability in mountainous or Himalayan Areas, as well as in adjacent areas.

These mountain ranges are characterized for their slope instability due to the inherent topographic, geological, geomorphological, seismological, hydrological and anthropogenic reasons. Consequently, hazards like earthquakes, landslides, mud slides, debris slides, rock avalanches, erosions, glaciated drifts and glaciated lake outburst floods (GLOF) are common phenomena. Water channels like rivers, nullahs and streams, lines of communication like highways, roads and tracks and built up areas like towns, villages, hutments and isolated houses, agriculture farms and orchard remains exposed to these hazards with variable level of vulnerability. The interaction between hazard and vulnerability leads to disaster in the form of blocking water channels like rivers, disrupting line of communications and washing away farms and orchards causing physical, social, psychological, political, economic and environmental impacts on those communities and people along with their infrastructure who suffer from these events.

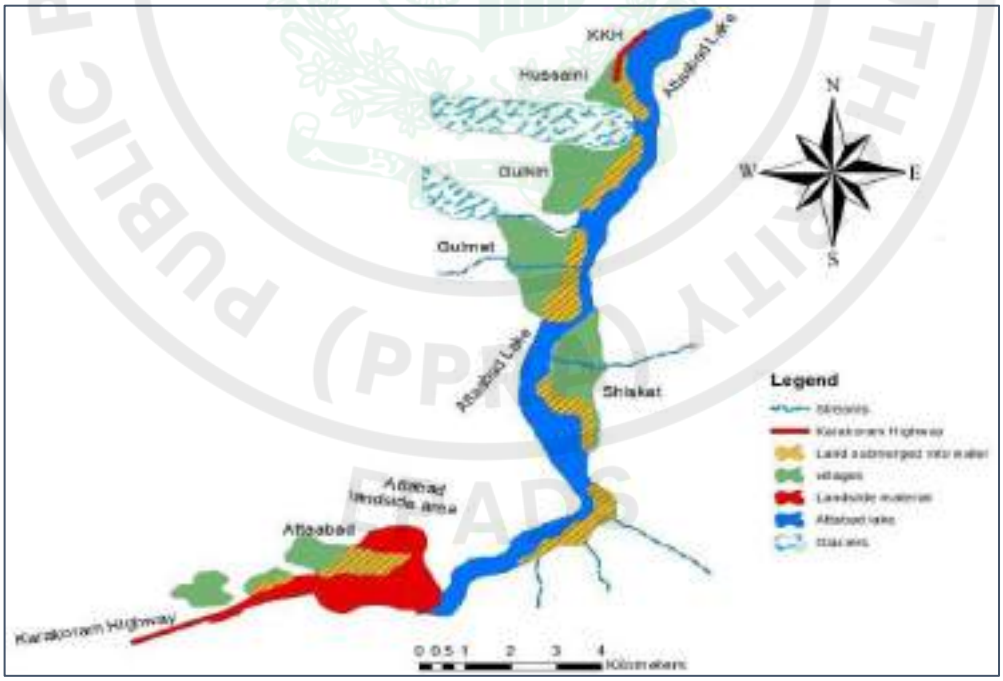

Figure 4-1 Attabad Landslide Area & Extent of Lake

January 4, 2010 is a day which witnessed a landslide hazard meeting with the vulnerabilities of Attabad and Sarat Villages, 109 km north-east of Gilgit and 20 km upstream from Karimabad in

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Hunza Valley, their farms and orchards, the River and Karakorum Highways (KKH) resulting into a historical event of creation of huge lake subsequently engulfing most parts of the villages like Ainabad, Shishkat, Gulmit, Gulkin and Hussaini into its fold.

4.2 HUNZA VALLEY

Karimabad, the capital of the Hunza Valley offers a panoramic view of high peaks like Rakaposhi. Nagar is the large kingdom across the river from Hunza. Passu is a village of farmers and mountain guides about 15 km away from Gulmit. This is the setting-off point for climbing expeditions up the Batura, Passu, Kurk and Lupgar groups of peaks, and for trekking trips up the Shimshal Valley and Batura Glacier.

4.2.1 Gojal Valley

Gojal with an area of about 8,500 km² is the largest tehsil of the Northern Areas of Pakistan. Lying in Upper Hunza, it shares border with China in the northeast and with Afghanistan in the northwest. Gulmit is the largest settlement of Gojal, commonly referred to as the capital of the tehsil. The main villages are Gulmit, Borit, Ghulkin, Hussaini and Passu which are well connected with other parts of the Region through KKH. Gojal has a population of about 20,000 with different ethnic groups of Wakhi and Burushaski. The dwellers of the area have mostly moved from Pamir areas of China, Afghanistan and Tajikistan and central part of Hunza.

There are parallel glaciers extend down to the main river valley from the upper catchments of mountain range between Gulmit and Passu. The Region is home to lofty ice capped peaks, roaring rivers, lush green pastures and long glaciers.

4.3 HUNZA RIVER

Hunza River is one of the main tributary basins of the Indus Basin River that contributes about 12% of the upper Indus flow, upstream of Tarbela Dam. About 80% of the total inflow into this dam originates from less than 20% of its contributing area, essentially from areas of heavy snowfall and glacierized basins above 3500 m a s l. About 50% of the basin area has elevations higher than 4700 m a s l.

The tributaries joining the Hunza River are Chapursan, Khunjerab, Ghujerab, Shimshal and Hispar Rivers.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Figure 4-2 Hunza River

4.4 HUNZA RIVER CATCHMENT

The Hunza River Basin lies in the high Karakoram Range within longitudinal range from 74º02' to73º03' and latitudinal range 35º54' to 37º05' in the Northern Area of Pakistan. It is bordered in the west by Gilgit River Basin, in the north by Afghanistan and China, and in the south by Shigar and Indus River Basins. The small portion in the north east of this basin drains in the Chinese territory. Most of the terrain of the basin falls in the elevation range of about 1,500m.a.s.l to more than 7,500 m a s l. The basin occupies an area of 16,389.4sq.km. The glacier cover of the basin is about 4,677.3 sq.km. The basin comprises of major valleys like Naltar, Nagar, Shimshal and Chapursan and hanging glaciers in the high Karakoram Range. A part of KKH passes across this basin linking Pakistan with China through Khunjerab Pass.

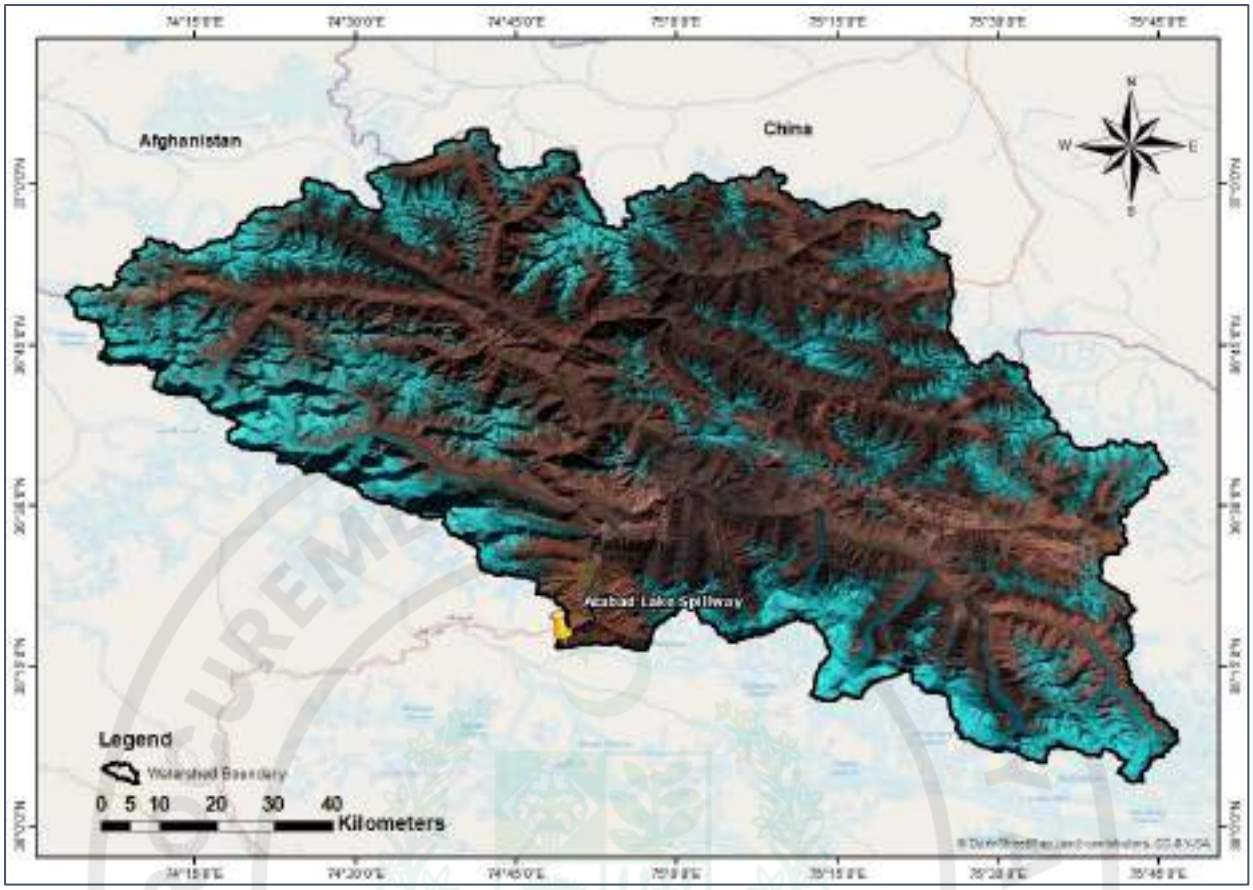

Figure 4-3 Attabad Lake Catchment Area with Landsat Imagery

4.5 CLIMATE

The Karakoram-Himalayan Region is glaciologically complex with high altitude source are as (above 4,500 m a s l) having perma frost and annual precipitation in excess of 2,000 mm while some of the large glaciers nouts extending down to semi-arid valley floors (2,700 m a s l) receive annual precipitation of less than 200 mm. The Karakoram area is influenced mainly by abroad scale weather system originating primarily from the Mediterranean or from the area of the Caspian Sea during the winter and spring seasons.

The Gilgit Meteorological Station is the nearest station to Hunza Valley that has a sound historical record covering more than five decades. Monthly temperature variations (maximum, minimum and mean) at Gilgit indicate parabolic trend with peak in the month of July. Summer prevails in months from June to August. In July and August, mean maximum and minimum temperatures are normally above 35˚C and 15˚C respectively. The winter is cold and chilly that starts from November and remain still end of March. The lowest temperatures are in the month of January when mean maximum and minimum temperatures reaches below10˚C and (-) 2˚C respectively.

The mean monthly rainfall data of Gilgit Climatological Station is available for the period 1951 to 2014. The available data has been processed to achieve annual, monthly and % monthly distribution of rainfall at Gilgit. The results so achieved are presented in Table 4 1. The mean annual precipitation for the period 1951 to 2004 is 186 mm. March and May are the months of maximum rainfall while the lowest rainfall occurs in the month of November. The graphical representation of average monthly and Min, Max and Average precipitation is given in **Figure**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4-4. The maximum daily precipitation recorded during the historic period is 48.3 mm in October 1987. The Project Area receives precipitation in the form of rain in summer and snow in winter.

Table 4-1 Annual & Monthly Distribution of Precipitation (mm) At Gilgit (1951 to 2014)

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Mean

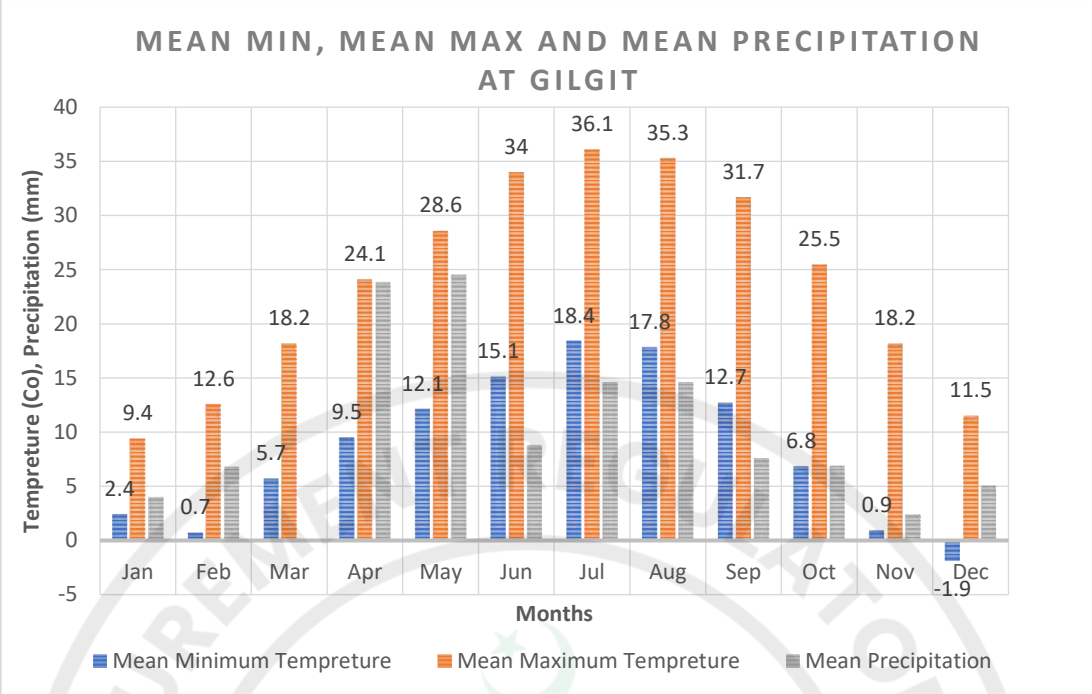

Figure 4-4 Mean Max, Mean Min and Mean Precipitation at Gilgit

4.6 ISOHYETAL MAP OF ATTABAD LAKE CATCHMENT

Although no data has been available to depict the precipitation pattern of the Hunza Basin, therefore, gridded precipitation data is used for the preparation of the isohyetal map to have a picture of precipitation distribution in the basin. Climate Hazards Group Infra-Red Precipitation with Station (CHIRPS) data for the last 20 years (2000 - 2019) is used for this purpose. CHIRPS was formed in collaboration of USGS Earth Resources Observation and Science (EROS) Center for reliable and up-to-date data sets.

The isohyetal map shows the mean annual rainfall of the basin for the last 20 years (2000 – 2019). Mean Annual Precipitation values vary from 88 to 485 mm. It is assessed that. precipitation is maximum near the Khunjerab Area and lower in the entire middle portion of the basin being the minimum near Misgar Village. Volume

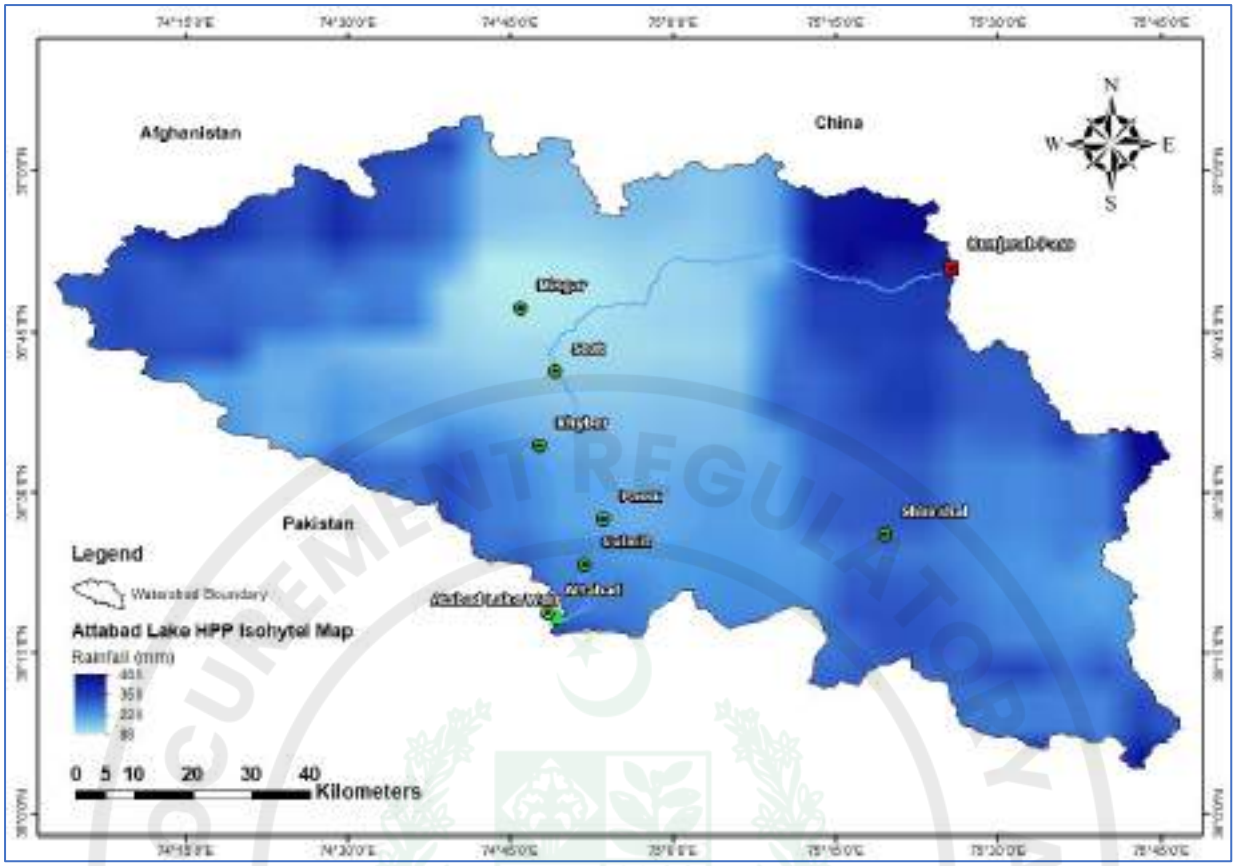

Figure 4-5 Isohyetal Map of Hunza Catchment

4.7 HYDROLOGY

The Karakoram and Himalayan mountains form the main source of snow and ice melt runoff to the Indus River System. The precipitation enhancing and shadowing effects of the main mountain ranges provide dramatic contrasts that greatly complicate the hydrological picture. The main tributaries of Hunza River are; Chapursan, Kilik, Bola, Das joining the Hunza River from the west and Khunjerab along with Ghujerab, Shimshal and Hispar Rivers joining river from the east of the valley. The river flows of Hunza are usually maximum in the month of July when snow and glacier melt is at its peak while these are minimum in the month of March when snow and ice melting is in significant.

4.7.1 Hydrologic Measurement Station

The hydrological data has been collected from Danyor station from the Surface Water Hydrology Project (SWHP), WAPDA located on Hunza River at Danyor Bridge.

Table 4-3 hydrologic Measurement Station at Hunza River

No	Name	River	Basin	Sub-basin	Latitude	Longitude	Elevation (m.a.s.l)	Catchment Area (km^2)
1	Danyor Br.	Hunza	Indus	Hunza	35°55’40’’	74 °22’35”	1,494	13,157

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.8 FLOW MEASUREMENT

There is no hydrological gauging station on Hunza River except one at Danyor Bridge being operated by SWHP-WAPDA. This station is located at about 107 km downstream of Attabad Land Slide Dam. The catchment area of Hunza River upto Danyor gauging station is 13,157 km^2, whereas it is14,083 km^2 upto its confluence with Gilgit River. Hunza River catchment area is 8,901 km^2 upto Attabad Landslide Dam. Therefore, river flows are transposed and estimated from documented discharge data from hydrological station at Danyor. Daily discharge data from 1966 to 2015 is available and processed for the calculations. Data for year 2016 was incomplete, therefore, it was not used in the calculations.

Mean annual flows are calculated and drawn in the figure below for the period 1966-2015. Average value for mean annual flow has been calculated as 208.36 m^3/s. Year 1973 witnessed the highest average flow of 310 m^3/s whereas, year 1997 witnessed the lowest average flows of 127 m^3/s.

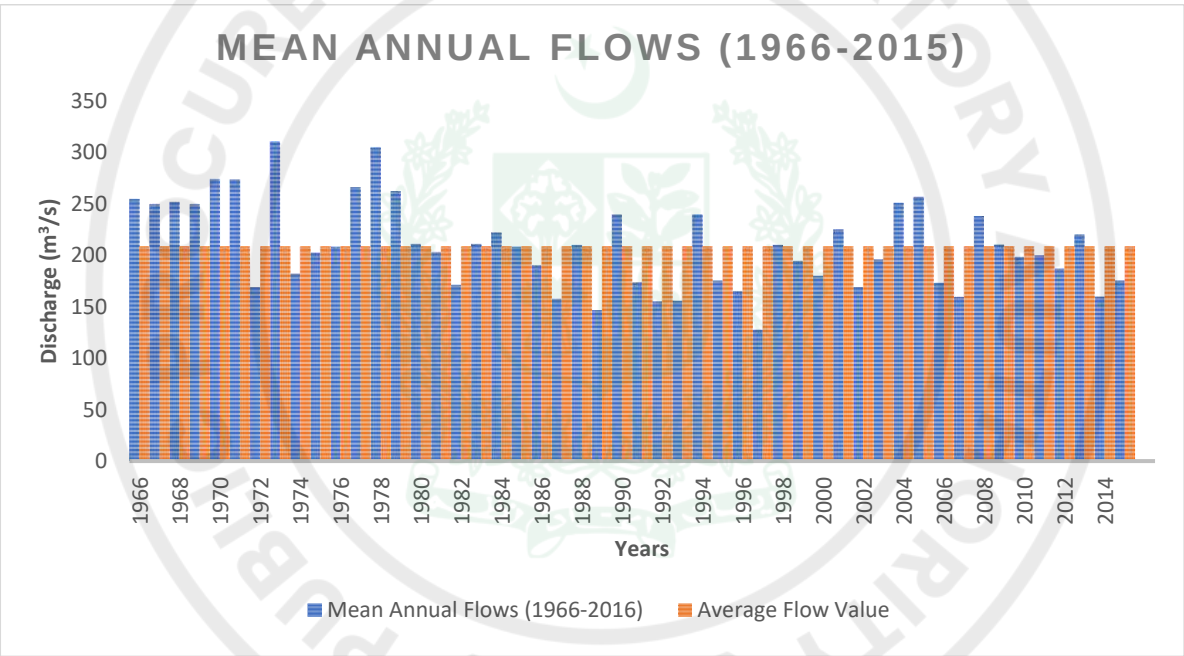

Figure 4-6 Mean Annual Flows

Mean monthly flows are estimated and plotted in the graph below. Flows are generally maximum in July and August reaching 700 m^3/s. Whereas, flows are low from December to April each year when snow falls in the catchment. The graph shows that design discharge of 60 m^3/s is available for about half year (almost 6 months). Graph shows that flows are exceeding the design discharge from June to October which shows the potential of hydropower generation.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

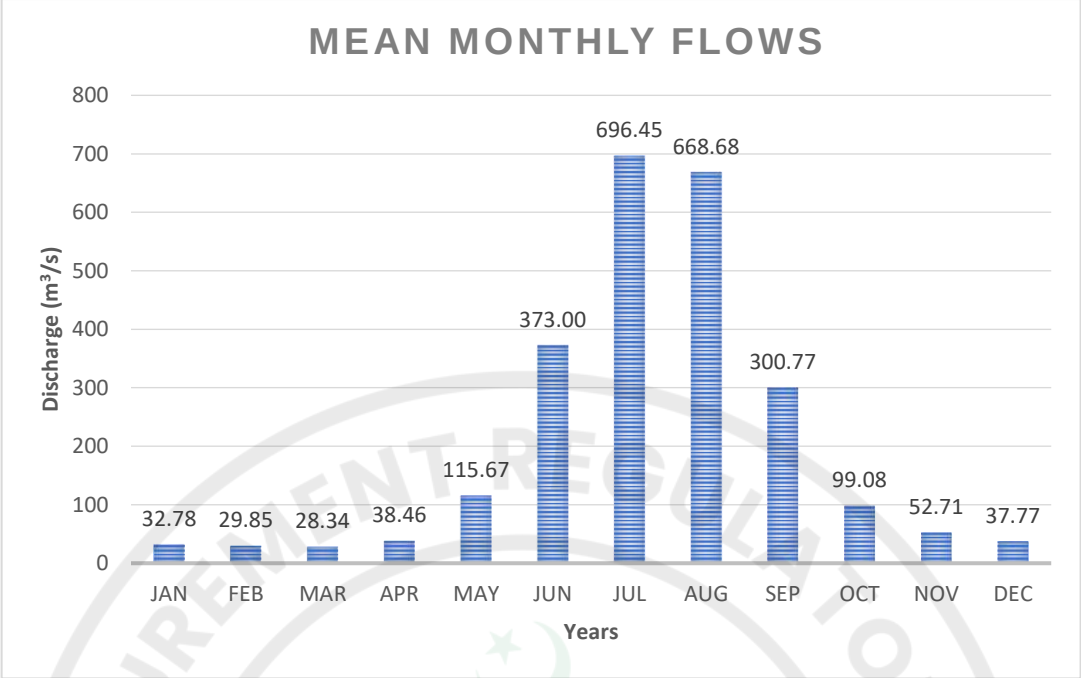

Figure 4-7 Mean Monthly Flows

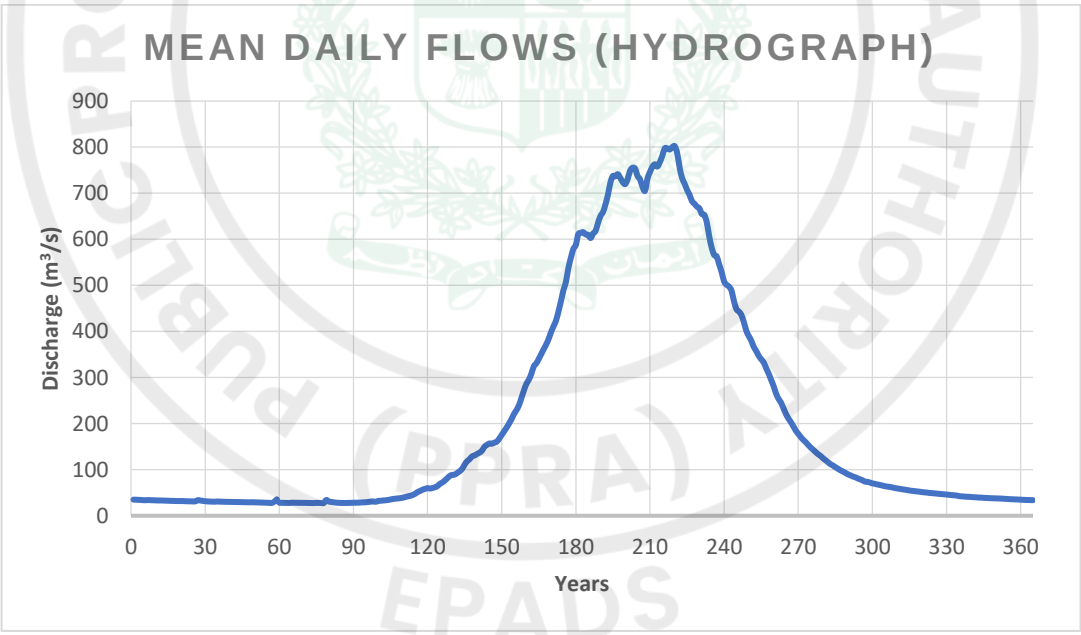

Figure 4-8 Mean Daily Flows

Mean daily flows are plotted in **Figure 4-8** which shows the sudden increase in flows after the fifth month and reaches to peak in July and August. Maximum, Mean and Minimum daily flows for the period 1966-2015 are also plotted in the **Figure 4-9**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

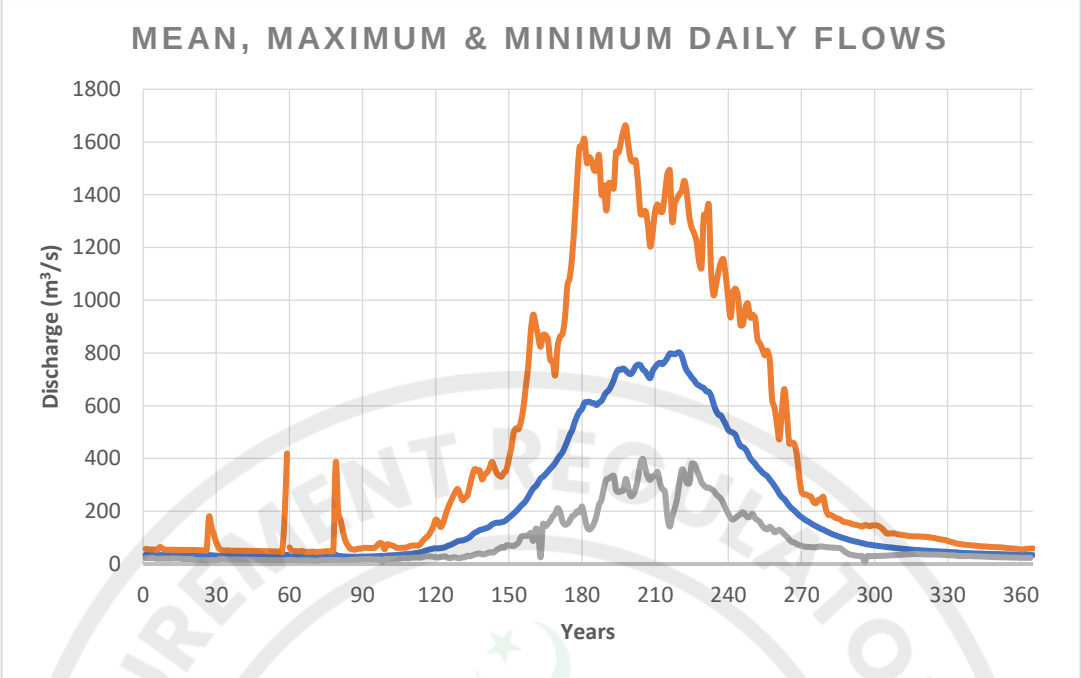

Figure 4-9 Mean, Maximum & Minimum Daily Flows

4.8.1 Flow Duration Curve (FDC)

FDC for ALHPP is plotted on the basis of almost 51 years (1966-2016). From FDC it us evident that design discharge of 60 m^3/s is available for almost 50% of the time. Therefore, design discharge of 60 m^3/s is justified for the generation of 54 MW power.

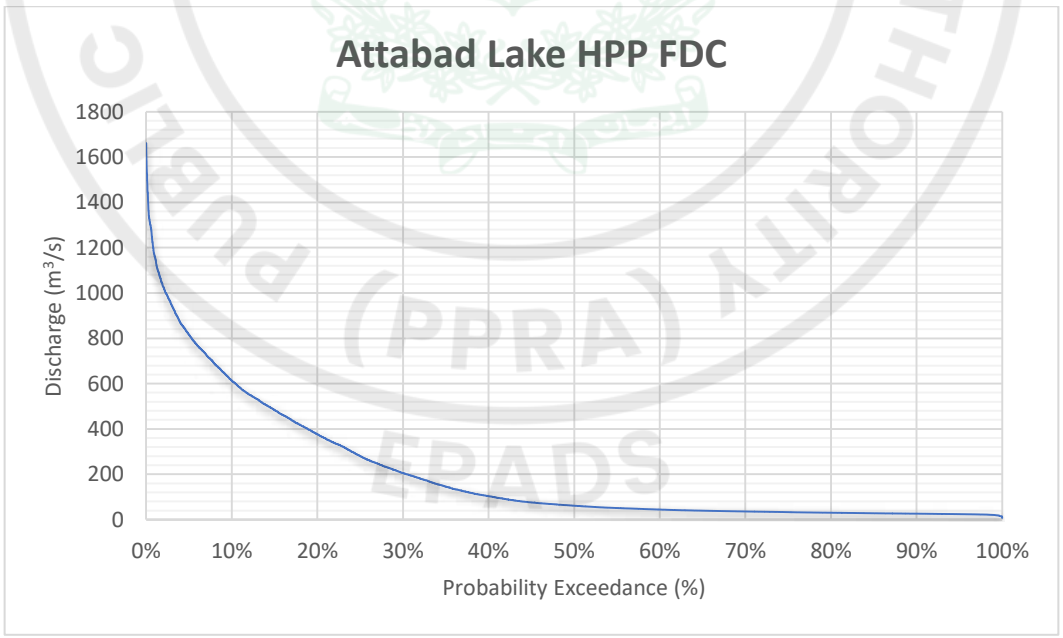

Figure 4-10 Attabad Lake Flow Duration Curve (FDC)

Table 4-4 Flow Duration Curve Results

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Probability Exceedance (%)	Flow (m^3/s)	Probability Exceedance (%)	Flow (m^3/s)
10	613.4	60	44.3
20	376.6	70	36.0
30	205	80	30.3
40	103.3	90	26.2
50	61.3	99	20.5

4.9 WATER LEVELS

The available head for power generation has been determined from normal operative level and the water level where tailrace channel joins Hunza River.

4.9.1 Upstream Water Levels

Upstream water levels have been determined keeping in view the operation of the Attabad Lake. For power and energy estimates, the normal operative level varies from 2,408 m.a.s.l to 2,412 m.a.s.l.

4.9.2 Downstream Water Levels (Tail-water Rating Curve)

The tail-water rating curve for downstream of the powerhouse at Hunza River is obtained using the water levels, historic discharges and cross section of Hunza River. Calculations are tabulated at **Table 4 5** and the tailwater rating curve is plotted at **Figure 4 11**. The downstream tail water rating has been adopted for stage estimation downstream of power house. The head losses expected to occur in the power scheme have been calculated to determine the net head available for power generation.

Table 4-5 Tailwater Curve Analysis

Water Surface Elevation (m.a.s.l)	Discharge (m^3/s)	Velocity (m/s)	Flow Area (m^2)	Wetted Perimeter (m)	Top Width (m)

4.10 FLOOD ESTIMATION

Flood has been estimated from the available record. The maximum peak discharges of mean daily for every year recorded. The instantaneous peaks will definitely be higher than the measured daily flows and can be enhanced while execution accordingly. Instantaneous peak flows for the period 1966 to 2015 has been calculated and plotted as well.

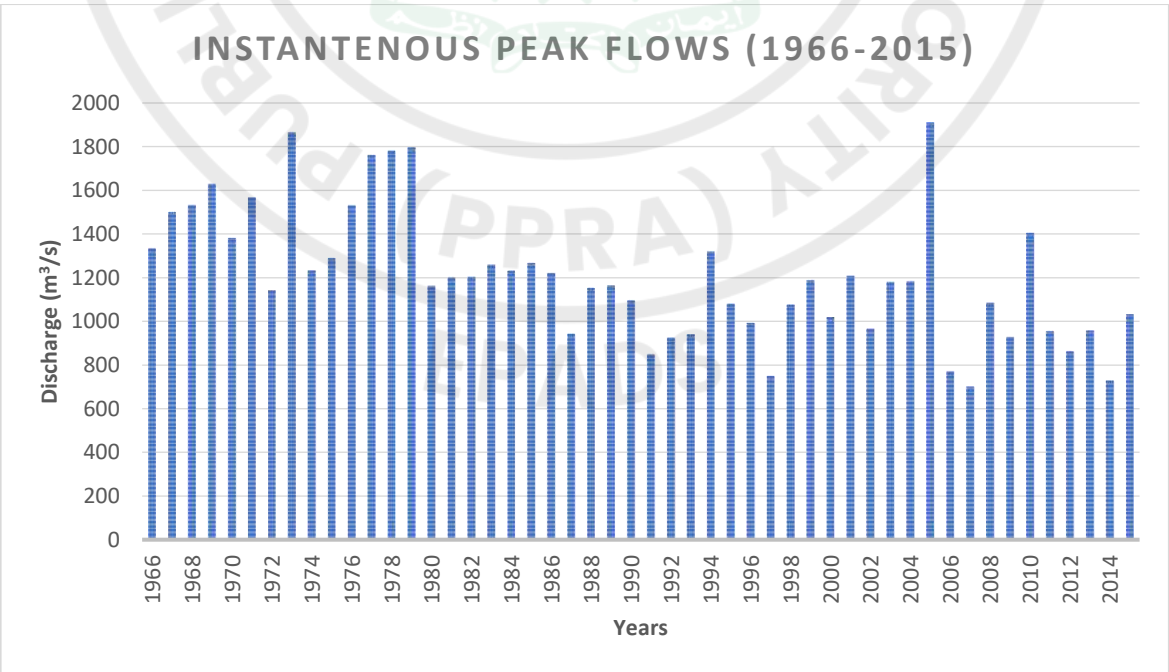

Figure 4-12 Instantaneous Peak Flows at Attabad Lake HPP Site

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.10.1 Flood Estimation by Flood Frequency Analysis (FFA)

Flood Frequency Analysis (FFA) has been carried out to estimate the flood at different return periods. Three types of distribution series namely Gumble, Normal and Log Pearson Type-III Distribution series have been used to estimate the flood.

The estimated values of floods from FFA of various return period at Attabad Lake site are tabulated in Table 4 6.

Table 4-6 Flood Frequency Analysis

Return Period (Years)	Gumble Distribution Estimated Flood (m^3/s)	Normal Distribution Estimated Flood (m^3/s)	Log Pearson Type-III Estimated Flood (m^3/s)
2	1,142	1,232	1,155
5	1,411	1,426	1,428

4.10.2 Flood Estimation by USACE HEC-SSP Model

Flood has also been estimated using the statistical model. The US Army Corps of Engineers (US-ACE) HEC SSP Model is used for this purpose. 17B Bulletin Method has been selected with Weilbul Plotting pattern in the model. Results of peak floods against percent chance exceedance been calculated and shown in **Figure 4-14**.

Figure 4-14 Flood Estimation using HEC-SSP Model

Flood Estimation using HEC-SSP Model. Confidence intervals of 5% and 95% have been used for the calculations.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

As per the model, flood for 1000-year return period from computed curve has been calculated as 2,559 m^3/s and from expected probability curve it is 2,695 m^3/s. Flood for 10,000-year return period, it is 3,016 m^3/s from computed curve and 3,292 m^3/s from expected probability curve. With the confidence interval of 5% and 95%, maximum flood values are 3,682 m^3/s and 2,606 m^3/s.

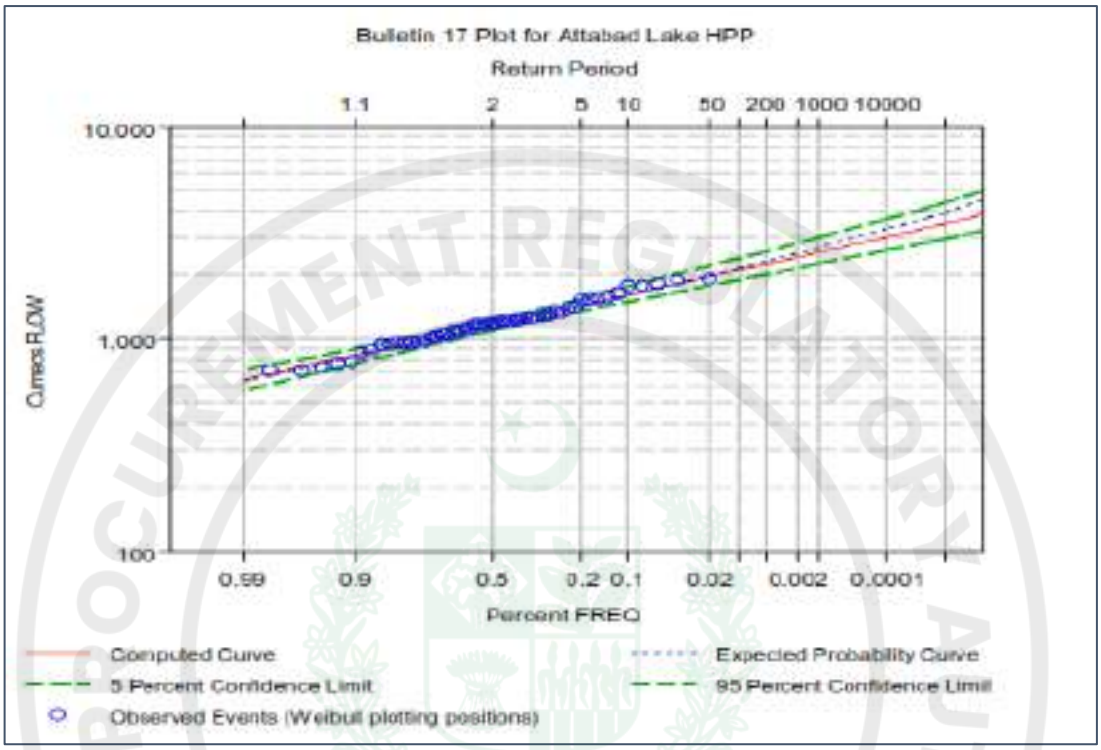

Figure 4-15 HEC-SSP Model Graph

4.10.3 Statistical Model Analysis

Statistical model results are tabulated at Table 4 7.

Table 4-7 HEC-SSP Model Results

4.10.4 Recommended Design Flood

Keeping in view the different types flood estimations and generation of high peaks due to GLOFs, it is recommended to adopt design flood of 10,000 years return period at weir site. Therefore, design flood of 3,250 m^3/s at weir site has been assumed for the calculations of design of structures.

4.11 HYDROLOGIC FLOOD ROUTING

Flood routing is a mathematical procedure for predicting the changing magnitude, speed, and shape of a flood wave as a function of time (i.e., the flow hydrograph) at one or more points along a waterway. Although, the lake has not much storage capacity but still it can lag and attenuate the peak generated by floods to minimize the adverse impacts on the downstream structures and areas. The temporarily stored water is then released through an outlet or spillway after the peak has passed.

U.S. Army Corps of Engineers' (USACE) Hydrologic Center's hydrologic Modeling System (HEC-HMS) is used for this Project. HEC-HMS uses level pool method also known as Modified Puls Routing method to route the flood wave. It uses the one-dimensional approximation of the continuity equation.

$$(Iavg - Oavg) = \frac{\Delta S}{\Delta t}$$

I_{avg} = Average inflow during time interval

O_{avg} = Average outflow during time interval

ΔS = Storage Change

Δt = Time Change

4.11.1 Establishment of the HEC-HMS Model

Attabad Lake catchment has been delineated using the ArcGIS tool which is then exported to HEC-HMS model. To model a reservoir, source, reservoir and sink elements are incorporated. Catchment area is shown at **Figure 4-16**. To setup the HEC-HMS model, Storage-Discharge relationship has been developed for the reservoir keeping the proposed outflow system. Storage-Elevation relationship is available from the hydrographic survey of the lake which is then used as paired data along with Storage-Discharge relationship for the hydrologic model. Inflow hydrograph has been generated keeping in view the peak discharge of 3,250 m^3/s. Time interval of 2-hours has been used for the hydrograph and simulation.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Figure 4-16 Attabad Lake Catchment Area Marked in HEC-HMS

4.11.2 Assumption for the Routing

The treatment of routing in this method is based on the assumption that the reservoir is level. This means that both the outflow and the storage depend only on the water level in the reservoir. It is not valid in reservoir where the backwater effect is such that a significant percentage of the temporary storage occurs as wedge storage between the sloping backwater surface and a horizontal plane extending upstream from the water surface elevation at the weir.

4.11.3 Results of Flood Routing

The routing exercise of the design flood was carried out with such scenario that outflow is being done by overflow weir (60 m in length) and assuming sediment flushing channel gates are not operating in case of flood. Under this scenario of discharge, the routed hydrograph is presented at **Figure 4-17** and results are tabulated at Table 4 8. As evident from the graph and table, it is deducted that the hydrograph with the peak of 3,250 m^3/s has been entered in the lake as inflow and attenuated peak of 3,085 m^3/s is attained after 4 hours of the inflow peak. The attenuated peak is attained at an elevation of 2421.3 m a s l. Thus, being a small level reservoir, Attabad Lake can play lag and attenuate the flood wave upto some extent as shown in the graph and table.

4.12 GLACIAL LAKE OUT BRUST FLOOD (GLOFS)

The most extensive glacier covers of the world outside Alaska and the Arctic is located in the Himalayan and Karakoram mountains. Pakistan is a home of more than 5000 snow reservoir and glaciers along with the second largest Siachen Glacier. The fresh water is preserved in these reservoir during the winter season and feed to the river in the summer season due to the gradual melting of ice and snow in upper parts of the country. They cover a surface area of 16,600 km2.Their runoff feeds the Hunza, Nagar, Gilgit and Indus rivers which in turn provide fresh water for about more than 100 million people residing in Indus Valley.

Lakes are water reservoirs existing in, under, beside or in front of a glacier, originated due to glacier ablation properties and retreat processes or damming of river valleys by advancing and/or surging glaciers. GLOFs result from the failure of natural dams formed from glacier ice and/or lateral and terminal moraines, which have impounded water. The moraines may be ice cored and contain unconsolidated debris, silt and large boulders. The lakes formed by these natural dams may vary in size from small marginal ice pools to lakes of several billion cubic meters.

The dams grow progressively owing to the glacier flow and deposition of debris. The advance and retreat process of a glacier contribute to the size and physical features of the moraine dams. They can rise to a few hundred meters in height. However, they are structurally unstable and likely to fail, as a result of overtopping, as a result of waves generated by avalanches and snowmelt and rainfall run-off, piping and sliding. The flood hydrographs arising from failure of glacial dams are attributable to several factors, such as the volume of the water in the lake, the height of the dam, the failure mechanism and the transient characteristics of the breach profile.

GLOFs are not a new phenomenon, however, with the current environmental and climatic changes, their probability has risen in most mountain ranges. Glacial lakes are particularly dangerous in the Karakoram ranges as they occur at low elevations and close to settlements. In some cases, potential outbursts allow only 10 to 40 minutes to trigger an alarm for the threatened population to evacuate to safety.

GLOFs can create two types of flooding:

- Upstream flooding as a result of impoundment, less dangerous for human life due to slow rise in water level but property damage can be substantial.
- Downstream flooding as a result of dam failure, significant threat to life and property.

Major glaciers of Hunza Watershed are:

4.12.1 Update on Glacial Hazards in the Upper Indus Basin

A study has been carried out by Reynolds International, through Diamer Basha Dam Company, using numerical simulations for the possibility of GLOFs in the Upper Indus Basin and their impacts on Diamer Baha Dam Project (DBDP). Numerical simulations have highlighted that a sudden breach of Shisper ice-dammed lake under the current condition should not pose a major threat to the safety of the Diamer Basha Dam (DBD). As per the report, using observational information available for a significant outburst from Shisper Glacier in May 2020, the dataflow software simulation outputs have been cross-checked and found to give reasonable agreement. The simulation shows that the 2020 Shisper outburst, the flood would only propagate for about 20 km downstream from the source.

It is suggested to have close monitoring of Glaciers in Hunza Region should be undertaken to have better judgment of GLOFs and remedial measures for the safety of Attabad Lake and downstream areas and comprehensive study will be undertaken during Detailed Engineering Design of the Project.

4.13 SEDIMENTATION STUDIES

4.13.1 General

Most of the rivers of Pakistan carry large amounts of sediment in suspension and as bed load. Much of the land in Pakistan is highly erodible because of sparse vegetal cover, steep slopes, and non-resistant soils and rocks. As a result, serious consideration must be given to the sediment aspects of rivers and sediment records imperative for a good design of water sector and hydropower projects.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The glacial lakes filled by moraines and ice core of retreating glaciers may breach suddenly due to unstable moraine 'dams', resulting in discharge of huge amounts of water and debris - known as 'Glacial Lake Outburst Flood (GLOF)'. The frequency of natural hazards like flash floods and GLOFs has increased in the Himalayan Region of Pakistan due to the global warming in recent decades. They often have catastrophic effects immediate downhill; even a small glacial lake associated with hanging glaciers poses high risk of a GLOF event.

According to Chaudhry, Mahmood, Rasul and Afzaal (2009), Pakistan experienced 0.76°C rise in temperature during the last 40 years. The frequency and persistence of heat waves in glaciated mountains has risen drastically causing rapid melting and sudden discharge of bulk of water to terminal lakes of glaciers increasing the risk of outburst. According to Goudie (1981) and Miller (1984), among 339 disastrous incidents identified along KKH in Hunza Valley in 1980, the most destructive ones were related to glacial movement that led to outburst floods of ice-dammed lakes.

The morphology of Hunza River has an important impact on the pattern of sediment transport. The River is a mountain river, where 98% of the catchment is built by mountains. The morphology of the River is characterized by boulders and gravels. The flow regime is mostly turbulent at lower reaches. The bed load of Hunza River and its flow regime are strongly influenced by the morphological structures of the area. The longitudinal water level profile is a parameter of the energy and shear stresses acting on the river bed and initiating sediment transport.

Sediment sources are glaciers, precipitation in the form of storms and heavy rains, hill slopes, landslides and gully erosion etc. The suspended load is influenced by availability of sediment sources and triggering events. In Karakorum and Himalayas large amounts of yearly suspended sediments per square kilometers of the catchment area (more than 2,000 tons/year/ km2) are reported in the river system. Based on the morphology, climate and flow regime of the area, the sediment load of the concerned catchment is thoroughly assessed.

The average sediment concentration is about 0.321% (by weight) or 3,210 ppm and the average suspended sediment yield per year is about 20.06 million metric tons. The observed minimum concentration is 2 ppm and observed maximum concentration is 21,300 ppm. Almost all of the suspended sediment is brought down by the river during the period of June to September. The river carries on the average, about 27% sand, 50% silt and 21% clay. The unit weight of fresh deposits of this sediment is about 1122.4 kg/m3.

4.13.2 Suspended Sediment Concentration

Normally, suspended sediments load and discharge observations are used to develop Sediment Rating Curve for the estimation of annual sedimentation of the reservoir. A relation between sediment concentrations and discharge is developed from available data of each year, and that relation or equation is then applied to daily flow series of each year to estimate annual sediment load at dam site. In this case for ALHPP, data of suspended load sediment concentrations is available from 1966 to 2015 at Danyor Station for the estimation of the annual suspended load calculation.

4.13.3 Sediment Sampling

The suspended sediment sampling of the Attabad Lake HPP at Daniyor is carried out from year 1966 to 2015. As per observed data, the number of suspended sediment observations taken

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

during Low-Flows period and High- Flows periods in each year are presented below in Table 4.11.

Table 4-11 Suspended Sediment Load Observations at Danyor

Year	Number of Observations During		Total Observations	Year	Number of Observations During		Total Observations
	Low Flows (Oct - Apr)	High Flows (May - Sep)			Low Flows (Oct - Apr)	High Flows (May - Sep)	
1966	5	4	9	**1990**	19	9	28

1983	5	13	18	**2010**	27	30	57
1984	12	15	27	**2011**	23	24	47
1985	13	13	26	**2012**	25	20	45
1986	5	7	12	**2013**	18	17	35
1987	14	15	29	**2014**	28	34	62
1988	9	8	17	**2015**	14	34	48
1989	17	12	29				

4.13.4 Sediment Grading

The particle size distribution of the sediment is an important parameter as it will determine the amount of the sediment that will be deposited in the reservoir and where and how long it will take to flush the reservoir. Very fine sediment may not be deposited in the reservoir and will pass through the turbines, or spilled when there is surplus inflow. On the other side, the coarsest sediment being carried by the river will be dropped first in the reservoir and will take longer to flush.

4.13.5 Available Data

There was limited sediment grading data available at the commencement of the study. The source of data came from the Surface Water Hydrology Project SWHP, (WAPDA) sampling at the Danyor Gauging Station between 1966 and 2015 and was in the form of proportions of sand, silt and clay, which have the following particle sizes:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Clay (< 0.0055 mm)
- Silt (between 0.0625 mm to 0.0055 mm)
- Sand (> 0.0625 mm)

The frequency of the readings is variable. In some years there were only a few readings and in others there are weekly readings. The percentage of sand in these readings varies between 36 and 85 %. The sieve analysis of suspended sediment samples carried out by SWHP (WAPDA) at Danyor Station showing mean fractions of sand, silt and clay of each year are given below in Table 4 12. The average percentage for all year of sand, silt and clay is 27.6 %,50.3 % and 21.6 % respectively.

As storage of a reservoir is mainly depleted due to the deposition of sand and coarse materials, while clay and fine silt remain in suspension even in low flow velocities.

1989	24.3	47.8	28				

4.13.6 Suspended Discharge Rating Curve

The sediment load versus river flow is a complex phenomenon. For the same value of discharge different values of the sediment concentrations in PPM can be obtained due to high variability of soil erosion on spatial and temporal scales. This is illustrated in **Figure 4 19** where discharge is plotted against observed sediment concentration in PPM to observe the variability of data. This scatter in values can be explained by initial flood flushes, the variability in the landslide triggering rates and abrasion of glacier fragments while sliding over the loose soil slopes. Intense rainfall over the lower part of watershed may also produce the variability in sediment discharges.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

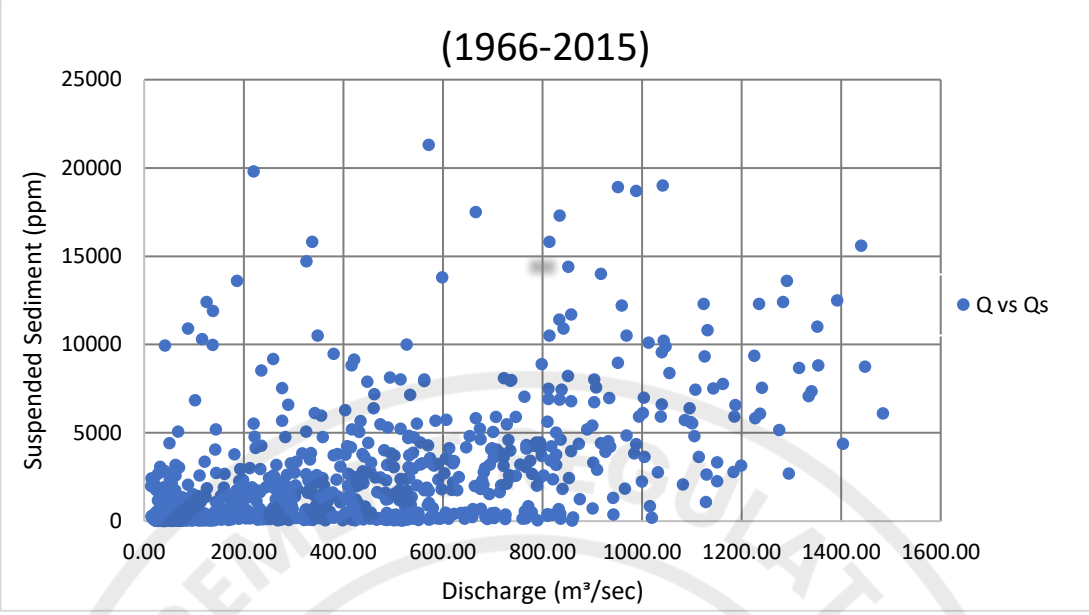

Figure 4-19 Danyor Sediment Concentration Data

Due to this variability, it is difficult to drive the relationship between discharge and sediment concentration as continuous and multiple recording of sediment concentrations would be required to obtain a complete understanding of the sediment regime. However, a general understanding may be obtained by pooling all the data and examining it on plot to obtain a trend line relationship, hence averaging the concentrations. Here, in this section, the suspended sediment rating curve is developed to estimate suspended sediment load at ALHPP site. The curve is developed by using data taken from Surface Water Hydrology Project (SWHP) WAPDA between sediment concentrations and corresponding discharge records as observed at Danyor station from year 1966 to 2015. The suspended sediment load in terms of metric tons per day is drown on scale against observed flows in Cumecs to get a relation between discharge (Q) vs sediment concentration (Qs) as shown is **Figure 4-20**.

The below Rating Curve is plotted based on 3 years' sedimentation concentration observations against their respective discharge. The equation of rating curve is applied to long daily flow series of each year to get annual suspended load as shown in Table 4 14 at Danyor station for year 1966 to 2015, thus the total average annual suspended load comes 33.43 Million Metric Tons with the range between 8.50 M Metric Ton and 90.35 M Metric Ton. The maximum annual suspended load for Danyor station is observed in 1978 i.e. 90.35 M Metric Ton.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

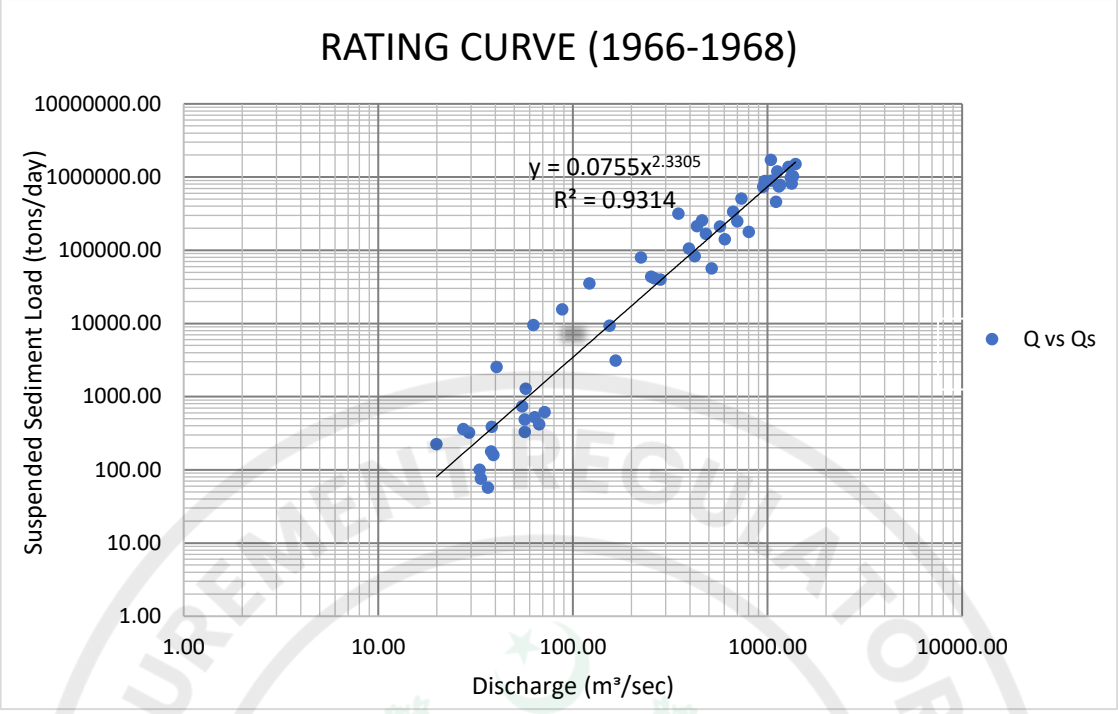

Figure 4-20 Suspended Sediment Rating Curve at Danyor Station

4.13.7 Sediment Yield

Hunza River is one of the rivers with highest annually sediment load due to major glaciers covering 18% of catchment area. Sediment load of the whole year and June to September is given in **Table 4-13** and sediment load computed at project site is available in **Table 4-14**. The table shows that river carries more than 89% sediment load during the four months of high temperature i.e. June to September.

Table 4-13 Percentage of Sediment yield for the Period of Jun to Sep to Total Yield of Year

Years	Jan to Dec	Jun to Sep	Percentage
	M Metric Ton	M Metric Ton	%
1966	46.74	46.44	99
1967	53.24	52.97	99

	Average		**33.43**

The mean annual suspended load (million metric tons) as shown in above table is also presented in bar chart in **Figure 4-21**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

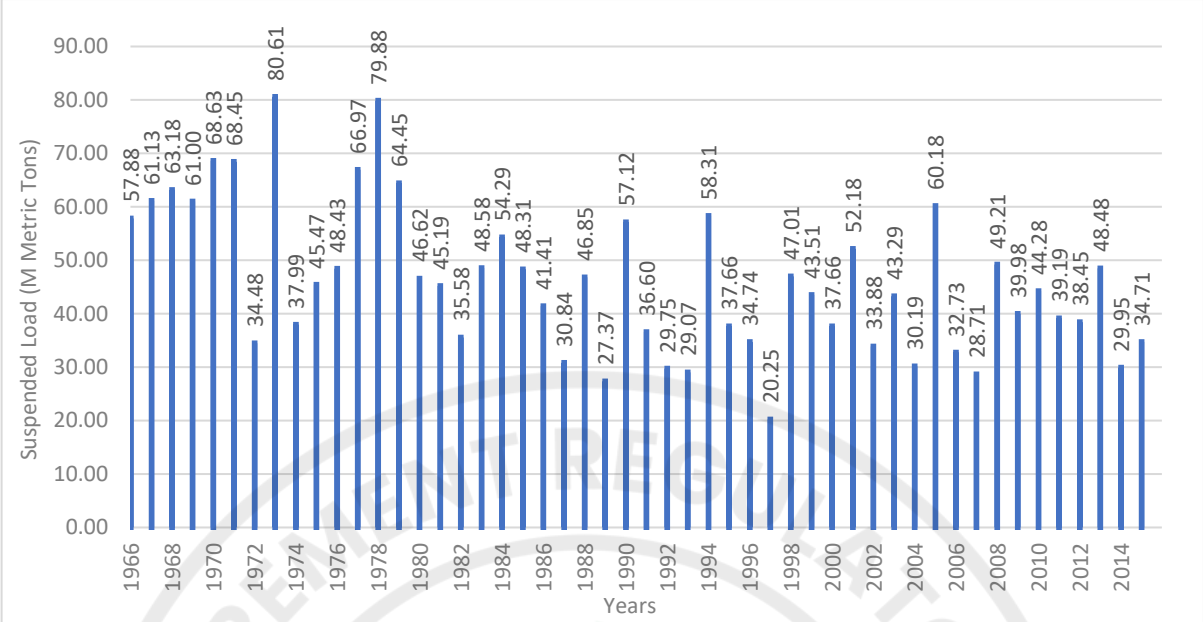

Figure 4-21 Average Annual Suspended Sediment Load at Danyor Gauging Station.

Average value of suspended sediment at Danyor comes out 33.43 MMT with data range 1966-2015 which falls on higher side and also differs from realistic value. To get a realistic value, we used lake capacity from recent hydrographic survey (2020), compared with 2010 capacity and do reverse calculation for sediment load which comes out about 20 MMT/year.

To remain on realistic side, we choose the period of 2011-2015 for the calculation of suspended sediment and the average of suspended sediment comes out 20.06 MMT.

4.13.8 Initial Density of Deposited Sediment and its Consolidation

Total sediment inflow to a reservoir is converted into volume by using the density of deposited sediment. In order to compute the initial density of deposited sediment, main factors are

i. The approach that is adopted to operate the reservoir and

ii. The texture and size of deposited sediment.

In present study, it was considered that reservoir operation is normally moderate to considerable reservoir drawdown. The same concept has also been adopted for the assessment of initial density of deposited sediment in this study. Therefore 561, 1140, and 1550 kg/m3 initial density of deposited sediment have been adopted for clay, silt and sand. The equation derived by Lara and Pemberton (1963) is used to estimate the initial density of deposited sediment which is:

$$W_o = W_cP_c + W_sP_s + W_{sa}P_{sa}$$

Where W0 is the initial density of deposited sediment, Pc, Ps and Psa are the percentages of clay, silt and sand, Wc, Ws, and Wsa are initial densities of clay, silt and sand. Initial density of the deposited sediment is thus computed as 1,122.4 kg/m^3.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The accumulation of sediment deposits changes the density of previously deposited sediments. The consolidation of settled material results in an increase in density with time. Miller's (1953) equation is used for the prediction of consolidation that is:

$$W_t = W_o + 0.434 (K) (t/t-1) *((\ln t) - 1)$$

Where Wt is the average dry bulk density after t years of consolidation, Wo is initial density and k is the compaction factor based on type of reservoir operation and sediment size analysis.

4.13.9 Mean Annual Sediment Load

Mean annual total sediment load is normally estimated by adding unmeasured sediment bed load to the observed suspended sediment load. The sediment volume is determined from the total sediment load and the unit Wi sediment weight. The average volume of fresh sediment deposits for Attabad Lake HPP is estimated as: (20.06 MMT x 1000 kg/MT) / (1122.4 kg/m3 x 1234 m3 /acre-feet x 106) ~ 14,483 Acre-Feet/ year.

4.13.10 Bed Load

The sediment load of a river is one of the key variables in channel dynamics. Plan form pattern, morphology, erosion, deposition and migration of the channel are in a large part determined by the amount of sediment moved by the flow in relation to the water discharge. A river may transport sediment in two distinct modes. In bed load transport, the sediment particles travel by rolling, sliding or hops of the length of a few grain sizes (known as saltation), and they are thus in frequent contact with the channel bed. On the other hand, in suspended load transport, the weight of the particles is supported by turbulent forces in the water and they can travel considerable distances without coming into contact with the bed. Herein, the dissolved load, which can be substantial, is ignored. Grains with sizes that cannot be found in the shifting parts of the bed in appreciable quantities are known as wash load, which in general is a part of the suspended load. Whether an individual particle is transported as suspended load or as bed load depends on particle size, weight and shape and on the ambient hydraulic conditions. Bed load can be defined as the rate of movement of sediments particles along the river bed in the process of rolling, sliding and / or hopping. It is very difficult to measure bed load by sampling as we do for suspended load. As such, no practical device for measurement of bed load in the field is used by any concerned department. Consequently, estimates of bed loads are not available at any gauging site in Pakistan.

Generally, the amount of bed load transported by a large deep river varies from 5 to 25 % of the suspended sediment load. For computing the bed load, several formulas or relations have been developed by various researchers and departments. Some of the earlier formulas, such as those of Schoklitsch, and Meyer-Peter and Muller, were based purely on experimental results. However, more recent formulae such as those of Einstein have a semi-theoretical background. All these formulas involve huge amount of field data. The application of these formulas is for theoretical consideration, and may not produce satisfactory results. Thus, by using the recommended guidelines, based on experience and observations, are considered acceptable for estimation of bed load.

Two guidelines have been considered. Firstly, a guideline presented by E.W. Lane and W.M. Borland (1951) as shown in **Table 4-15**: according to these guidelines the bed load being transported by the Hunza river based on the Daniyor sediment concentrations may range from 10 to 35 %. Secondly, the USBR guidelines (1987) based on the Modified Einstein Procedure.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

In these guidelines, which are reproduced in **Table 4-16**, five conditions are given for defining bed load dependent on suspended sediment concentration and size analysis of river bed material and suspended materials. According to this procedure, Condition 2 is close to the river bed conditions. This gives a recommended range of the bed load in terms of suspended load of 10 to 35 %. In view of these recommendations, a bed load concentration of 20% of the suspended sediment has been adopted. Here to calculate bed load of sedimentation of Attabad Lake HPP, 20% of suspended load has been taken as un-measured sediment load. Therefore, the annual bed load for Attabad Lake HPP site is estimated to be 4 Million Metric Tons.

Table 4-15 Lane and Borland Guidelines for Estimating Bed Load

Condition	Suspended Sediment Concentration (ppm)	Stream Bed Material	Texture of Suspended Material	Bed load in Terms of Suspended Load (%)
1	< 1000	Sand	Similar to bed	25 to 150
		Compacted clay	Small amount of sand	5 to 12
		Gravel, cobbles & boulders	Small amount of sand	5 to 12
2	1000 to 7500	Sand	Similar to bed	10 to 35
		Compacted clay	25% sand or less	5 to 12
		Gravel, cobbles and rocks	25% sand or less	5 to 12
3	> 7500	Sand	Similar to bed	2 to 8
		Compacted clay	25% sand or less	2 to 8
		Gravel, cobbles and rocks	25% sand or less	2 to 8
4	Any Concentration	Clay and silt unconsolidated	Silt and clay	< 2

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 4-16 USBR Guidelines for Estimating Bed Load

Condition	Suspended Sediment Concentration (ppm)	Stream Bed Material	Texture of Suspended Material	Bed load in Terms of Suspended Load (%)
1	< 1000	Sand	20 to 50% Sand	25 to 150
2	1000 to 7500	Sand	20 to 50% Sand	10 to 35
3	> 7500	Sand	20 to 50% Sand	5
4	Any Concentration	Compacted clay, gravel, cobbles, or boulders	Up to 25% sand	5 to 15
5	Any Concentration	Clay and silt	No sand	< 2

4.13.11 Trap Efficiency

Trap efficiency (TE) is the proportion of the incoming sediment that is deposited, or trapped, in a reservoir or pond:

$$TE = \frac{S_{inflow} - S_{outflow}}{S_{inflow}} = \frac{S_{settled}}{S_{inflow}}$$

Where:

S_{inflow} is the sediment mass entering a reservoir (the sediment yield or delivery);

$S_{outflow}$ is the sediment mass leaving the reservoir with the outflowing water;

$S_{settled}$ is the sediment mass deposited within the reservoir.

The TE of reservoirs and ponds is dependent on several parameters (an overview of the processes taking place in a reservoir is given by Heinemann, 1984). Since TE is dependent on the amount of sediment deposited, parameters controlling the sedimentation process are very important. Therefore, the particle-size distribution of the incoming sediment controls TE in relation to retention time (i.e., the average time the incoming runoff remains in the reservoir or pond). Coarser material will have a higher settling velocity, and less time is required for it to be deposited. Very fine material, on the other hand, will need long retention times to deposit.

The particle-size distribution of the incoming sediment is dependent on the soils in the catchment that are being eroded and on the sediment delivery processes. The retention time of a reservoir or pond is related to the characteristics of the inflow hydrograph and the geometric characteristics of the reservoir or pond, including storage capacity, shape and outlet typology. A small runoff volume will have a larger retention time for a given pond than a very large runoff event, whilst the distance between the inlet and outlet controls the time it takes the runoff water to leave the reservoir or pond. The shape of the reservoir or pond (e.g., expressed as a stage-area curve) can also govern the retention time. Similarly, the location of the principal spillway can also control the retention time. If located at the bottom, the water will flow out directly while, if it is located at the top of the embankment, the runoff water will, first, have the opportunity.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Two methods are widely being used for the estimation of trap efficiency i.e. the method of Brune (1953), which is based on the capacity-inflow ratio and the method of Churchill (1948), which is based on a sedimentation index obtained by dividing the retention period by the average flow velocity in the reservoir.

US Army Corps of Engineers (1989) developed a regression using Brune's curve to estimate trap efficiency (T.E), which is:

$$T.E = 100 \times 0.97^{0.19^{\log (S/I)}}$$

Where S is the storage and I is the inflow rate. Using this equation, initial trap efficiency is to be 58% and its value decreases as the reservoir is silted up progressively

4.13.12 Life Assessment of Attabad HPP Reservoir

According to UNESCO (1985), life of a reservoir is the time from first impoundment till it is filled with sediments to a certain point, where it no longer serves the intended purpose.

For Attabad HPP, initial trap efficiency was estimated to be 58%. In order to do the reservoir sediment empirical modeling, the average sediment inflows have been taken as

24.06 million metric tons. Furthermore, an initial density of 1,122.4 kg/m3 has been used for the conversion of sediment load to sediment volume. By using above sediment flow in Attabad Lake, it will be filled in 10 years. So, reservoir life of the Attabad Lake HPP is about more than 11 years without flushing. **Table 4-18** shows in detail the life of reservoir

5 GEOLOGY AND GEO TECHINCAL STUDIES

5.1 GENERAL

Geologically, the Project Site is located in Karakorum Block (KB) further to the north of Main Karakorum Thrust (MKT). The Karakorum Block consists of sedimentary, metasedimentary, igneous as well as metamorphic rock, throughout its extension from Karakorum Fault (KF) in the east, Chaman and Herat Fault in west (Zanchi 1993) ranging in age from Precambrian to Cretaceous. The overburden material, consist mainly of Angular Boulder Gravel with sand and appreciable amount of fines (ABGM) and Rounded Boulder Gravels with sand and appreciable amount of fines (RBGM). The talus deposits are main constituents of ABGM and well developed mostly in Shamshal Valley and along Hunza River in upstream reaches. There are many evidences (the deposition of clayey silt along both banks of Hunza River) along the road indicate that river might be chocked many time in recent past. Prior to Attabad slide, the slope failure occurs at Salmanabad in 1958 and chocked the Hunza River.

The topography and geological conditions present in this valley indicate that it is glacial originated valley modified later on by river system. There are many glaciers that feed the Hunza River, from south to north i.e. Hassanabad, Gulmit, Gulkin, Passu, and Batura Glaciers, from right side and Shamshal Valley Glacier from left side. Morphologically the valley is lithological as well as structurally controlled. Weak lithology i,e slates as well as fault system attributed to the development of present shape of the Hunza Valley in upper reaches and near MKT.

This report is mainly based on the annotations observed during geotechnical investigations carried out at Attabad Lake Hydro Power Project (ALHPP). The geological and geotechnical investigations include Surface Geological Mapping, Drilling at weir site, sediment flushing channel/undersluice, head race tunnel and powerhouse area, and identification of borrow area for construction material. Samples collected during geotechnical investigations have been tested to ascertain geotechnical properties at Central Material Testing Laboratory (CMTL), Lahore.

5.2 SCOPE OF WORK

During the Feasibility Study (FS) of ALHPP, Hydro Planning (HP), WAPDA, has identified the deficiencies of geotechnical investigations in pervious Feasibility Study and carried out detailed geotechnical investigation for comprehensive FS at present. The layout plan was completely changed during present FS and investigation were conducted according to new layout. One of most important aspect is Neo-tectonic studies, because this area is affected by Attabad Slide in 2010. It is very important for the development of hydropower Project in this area to develop the understanding the Neo-tectonic setting operating under regional tectonic forces for the stability and planning of the hydropower Project. All the geotechnical data collected during geotechnical investigations have been utilized for foundation evaluation of all structures of ALHPP.

5.3 REGIONAL GEOLOGY

The Project Area lies in the KB bounded in north by Central Pamir through Rushan Pshart Suture, in east by KF, in the west by Herat Fault and in south by Kohistan Island Arc (KIA) through Main Karakorum Thrust (MKT) (Pashkov & Shvol'man, 1979 & 1981). The Karakorum Block have classified as a part of Gondwana Land in pre-collision history. The rocks of KB have

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

stratigraphic association with rocks of Indian Plate as indicated by Paleozoic to Mesozoic sequence of both plates. It is likely to be considered that Karakorum micro plate and Indian Plate were united till Mesozoic Era.

The stratigraphic sequence of the KB is metamorphic equivalent of sedimentary rock in Indian Plate which shows that both plates have pre-collision similarities. Also the KB consists of sedimentary (well exposed is in Chitral Area along Mastuj River), igneous rocks (Karakorum Batholith) and metamorphic rock (slates, schist and marbles).

5.3.1 Stratigraphic Sequence

The area under study mostly includes part of the Northern Karakorum Terrain, which comprises intensively folded and thrusted sedimentary rocks with a very low metamorphic imprint, locally reaching low grade conditions (Zanchi,1993). The Lower Permian to Upper Cretaceous succession of the North Karakorum represents one of the few terrains which escaped strong metamorphism during the Indian-Eurasian collision, thus permitted a detailed reconstruction of its stratigraphic framework **(Vol-2, DWG-1301)**. Plutonic bodies mainly of mid-Cretaceous age intruded the sedimentary cover forming a discontinuous granitic belt developed about 100 km north of the Karakorum Axial Batholith (KB). Four main tectonic units have recognized in the Project Region (Gaetani et all., 1990). These include;

5.3.2 Misgar Unit (MU)

This unit consist mostly of slates, with few intercalations of metacarbonate quartzite and black terrigenous slates, mostly exposed at the Northern part of the Project Area. In some areas, its thickness increases up to thousand meter. It is strongly folded with intensive developed of slaty cleavage. The fold axes generally trend E-W up to the Khunjerab Pass, where they turned to NNW-SSE. The unit has low grade metamorphism indicated by chlorite, biotite, and muscovite. This unit is intruded by granitoide pluton in northern and eastern terrain having western extension up to Sost. This unit belongs to different stratigraphic formations of Paleozoic age.

The southern boundary of Misgar Unit is faulted with south vergent thrust plane, the northern fault stacking the Misgar Slate over Jurassic limestone and sandstones of Sost belt (Gaetani et al. 1990). Large recumbent folds present along the northern flank of the Chapursan Valley suggest southward movement of MUT.

5.3.3 Sost Unit (SU)

It consists of grey to dark grey slates, meta-limestone, and quartzite. At places, it has dolomitic patches (Gojal Formation). Some sandstone beds with slate intercalations overlain by argillaceous limestone are present (Gircha Formation). It comprises thick pile of folded and thrusted sheets forming in the whole antiformal stack, later disrupted by strike-slip faults. The unit is bounded by two major faults, the Upper Hunza Fault (Desio, 1979) to the south-east and the Northern Fault to the north. Complexity of the tectonic pattern often prevented the reconstruction of continuous stratigraphic successions, as in the Middle Late Jurassic sediments. Fold axes and fault striations along the main thrust surface generally indicate a N-S compression. The well-developed schistosity is defined by sericite, muscovite and fine grained biotite with occasional occurrence of epidote and chloritoid. This suggests that low grade condition of metamorphism with an important increase of temperature with respect to other thrust sheets of the SU. These shear zones is still poorly understood and may possibly be related to the eastward prosecution of Hunza Fault (HF) juxtaposing the Gircha Slates of Gojal

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Unit to analogues metasediments of Sost. The stratigraphic succession present in the SU spans from Permian to Late Cretaceous.

5.3.4 Gojal Unit (GU)

This tectonostratigraphic unit was defined by Gaetani et al. (1990) and includes the sediments lying between the KAB and the Upper Hunza Fault (UHF). It is composed by two units, a terrigenous unit (Passu Slates) below and a calcerous-dolomitic unit above. In the lower Shamshal Valley, dolomitic marbles terminate along a sub vertical NS trending fault while southward this unit is intruded by KAB. Contact metapelites generally undeformed or poorly deformed intrusive that grades into biotite, muscovite, and andalusite. Folds within the unit trend from NW-SE to NNW-SSE and are generally NE-facing. Thrust planes show the same trends and are NE-vergent, as in case of UHF.

5.3.5 Karakorum Axial Batholith (KAB):

The KAB crops out along the southern part of the studied area, where two major plutonic complexes were recognized, the Hunza and Batura Units (Debon et al., 1987). The Hunza Unit exists in a huge plutonic unit extending for more than 250 km, made up of medium grained granodioritic in composition, locally recrystallized. They represent a calc-alkaline association. Mafic enclaves of various sizes are abundant and a conspicuous network of Cenozoic leucocratic dykes is locally present.

The Batura Unit (BU) intrusive, spanning in age from Paleocene to Eocene, is mostly new, as well as the findings of plutonic bodies belonging to this unit in upper Chapursan Valley. The BU includes two main intrusive; the Kuk and Sarbzea Plutons.

The Kuk Pluton consists of pinkish, undeformed and unfoliated granitoides of various grain size, locally with porphyritic, microgranular and rapakivi textures. The Sarbzea Pluton mainly differs from the Kuk Pluton by its very coarse to medium grained rocks, and sometimes by the deformation it had under gone.

5.3.6 Ganesh Formation:

This Formation consists of pelite-psammite turbidite unit and overlying calc-pelite marble unit and are intercalated with each other. These units are metamorphosed up to upper amphibolite facies and therefore have well developed sheets of amphibolite. The formation has well developed ruby and spinal. Different mines are also established in this unit, as can be seen along road near Ganesh Bridge.

5.3.7 Hassanabad Granite:

It is well exposed in the Lower Hunza Valley and consists mainly of lower s-type granitoid-migmatite complex with metasedimentary enclaves. These garnet-tourmaline bearing two mica granitoids and migmatites are well exposed in Hasanabad Nullah and in Hunza Valley along Hunza River.

5.3.8 Chalt Formation:

It consists of dark grey quartz biotite schist with subordinate quartz, marble and conglomerate. It is exposed along overturned anticline and faulted against Dumordo Formation. Permo-Carboniferous age is assigned to this Formation.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5.4 REGIONAL TECTONICS

Before the Northward flight of the Indian Plate, small continental pieces (Cimmerids, i.e. KB, Helmand Block, Hasha Block etc.) were broken up from the northern edge of Gondwana Land and welded with the southern edge of Eurasian Plate, consuming the Old Tethey and opening the Neo Tethey, (Tapponnier, 1975, 1977; Molnar, 1977a).

In general, due to the subduction of the oceanic part of the Indian Plate beneath the Eurasian Plate, the Island Arc emerged in Middle Cretaceous age. The Arc Complex consists of calc-alkaline plutonic rocks mainly mafic in nature. The presence of blue schist metamorphism in Swat and Shangla Areas indicate the trench environment.

The collision of the Indian and Asian plates has been described as a “head on” north-south collision (Shackleton and Ries, 1984). This is generally accepted by many workers to have occurred in Eocene times (55-40Ma) (Powell, 1979; Klootwijk et al, 1979; Dewery et al, 1988; Treloar and Coward, 1991; Serrle et al, 1987, 1988). The terminal collision between Indian and Asian Plates is suggested to have occurred between 45-40 Ma (Molnar and Tapponnier, 1975; Klootwijk et al, 1985). It is generally agreed, however, that by 55Ma, the Kohistan Island Arc (KIA) was already sutured to the Asian Plate, probably since the Late Cretaceous, forming the MKT zone. This is confirmed by the presence of 85-80 Ma thermal event at this time (Treloar and Rex, 1990). The collision between the Indian Plate and KIA is recognized as when the Tethyan Ocean disappeared and the continental masses docked. Following features recognized the main arguments for the Eocene age of collision: -

- Sediments deposited on the northern margin of the Indian Plate being of Eocene age.
- Subduction of the oceanic crust stopping, as recognized by the end of calc-alkaline magnetism north of the Indus Suture.
- The blue schist facies are not developed along MKT zone showing the collisional belt.
- Slowing down of the Indian Plate motion, as recognized by magnetic anomalies.
- After collision, continued suturing occurred, associated with a 35˚ anticlockwise rotation of the Indian Plate relative to Eurasia. As a result of collision mighty mountain ranges of Himalayas were developed having Island Arc Sequence in the North.

Anticlock wise rotation of Mega Lhasa followed the Late Triassic docking of the Iranian Spur, using the later as pivot. The rotation was completed during the Middle Jurassic, when SE Pamir, Shaksgam and Karakorum joined the Qiangtang, more closely assembling Mega Lhasa as it approached the Asian margin (Maurizio Gaetani, 2007). The KB bounded in the East by KF, in the North by Rushan- Pshart Suture, in the west by Herat Fault and in south by MKT.

Structurally the KB is characterized by broad asymmetrical to tight, isoclinal folds which are commonly imbricated. A number of large regional scale thrust faults, e, g. the Tirchmir Fault, Reshun Fault, Baltit Fault, UHF, and Chapursan Fault and the MKT extends for a distance up to 100 km or more. The KB has undergone multiple deformations since the Cambrian. Parts of the KB have undergone at least four more deformations since the Kohistan-Karakorum collision from Paleocene to Pliocene.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

After the collision, due to further northward subduction of the Indian Plate, still active 2-2.5 mm/yr, the stresses were accommodated by the imbricate thrust faults from north to south (Treloar et al, 1989). The collisional history along with metamorphic events, trapped many clues between these fault systems. These are very useful to delineate the historic events and to reveal the movement of Indian Plate, collision environment and modern deformational style.

5.5 REGIONAL FAULTS

The major regional faults of the region include, from north to south, the MKT, Main Mantle Thrust (MMT), Panjal Thrust (PT), Main Central Thrust (MCT), Main Boundary Thrust (MBT), Kashmir Boundary Thrust (KBT) / Himalayan Frontal Thrust (HFT) and Salt Range Thrust (SRT) **(Vol-2, DWG-1302)**.

Along with these regional faults, many local faults were developed to accommodate the regional stresses, these may be thrust fault or strike slip fault in nature. In most of the area many small scale strike slip faults are associated with the thrust faults to accommodate the deformation.

The general trend of these faults excluding MKT is predominantly east-west with change in trend due to syntaxial bends. The general description of these major faults is as follows: -

5.5.1 Karakorum Fault (KF)

Dextral Strike Slip fault of about 800 Km long bounds western Tibet. The KF represents a much younger terrane boundary, juxtaposing rocks of the Ladakh and Saltoro Blocks to those of Karakorum terrane. U-Pb zircon age of leuco-granites intrusion shows that it must, therefore, be younger than 15Ma old. Movement on the fault displaces the sequence approximately 200-250Km to south eastern Tibet where the regional rock sequence can be regained (Burtman et al. 1963, Srimal 1983). It merges at the confluence defining a triple point and three blocks; the Ladakh block to the south, Saltoro block to the northwest, and the Karakorum block to the northeast.

A number of tele seismic events have occurred along the fault. Interpretation of seismic data from 1975 Kinnaur earthquake confirms right-lateral strike slip motion on this fault. Three events were recorded from KF Zone at the head of the Nubra Valley, since 1980, recorded by portable seismic stations, established by International Karakorum Project (IKP). It is seismically an active fault.

5.5.2 Upper Hunza Fault (UHF)

It is east west trending thrust fault that runs along the depression formed by the Chapursan and Upper Yarkhun Valleys (Zanchi 1973, Kazmi 1979b, Gaetani et al. 1995). In this region it runs parallel to the northern margin of the KAB. Southeast of Morkun (upper Hunza) three tele seismic events of magnitude 5-7 and focal depth of less than 50km have been recorded. These epicenters form a cluster very close to the mapped trace of the UHFt. It means that the northern and western margin of the KAB is characterized by active zone of faulting along Upper Hunza-Reshun Fault zone.

5.5.3 Main Karakorum Thrust (MKT)

The MKT is a low angle mega-shear with strike slip component, which on eastern side passes through Machlu in Hushe Valley, Shigar Valley, Zuhri Brook in Shyok Valley and Chalt in Hunza

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Valley extends westward through Ishkuman, Yasin and Shishi Valleys **(Vol-2, DWG-1302)**. Its general trend swings between E and E-NE at low to medium dips towards the north. It is believed that this fault is seismically active.

5.5.4 Main Mantle Thrust (MMT)

The MMT, which is aligned with the Nanga Parbat-Haramosh tectonic line on east, span an area of about 400 km through Diamer, Kohistan, Swat, Dir and Banjaur Areas, before entering Afghanistan **(Vol-2, DWG-1302)**. The general trend of MMT is NE-SW. It is located along the contact of the mafic/calc-alkaline meta igneous rocks and the meta-sediments belonging to the Indo-Pakistan continental mass. Along this megashear near Jijal Village on Indus River (right bank), the igneous rocks have over thrusted the meta-sediments to the south over a 10-15 km wide zone. The thrust also manifests as the broad high topography of Kohistan relative to the Hazara adjacent to the south. In addition, numerous auxiliary fractures are developed and across the thrust frequent brecciation and mylonitization are also present along the contact. It is seismically active fault.

5.6 SITE GEOLOGY

5.6.1 Soil Units

The recent deposits are the most widely spread soil units overlies the bed rocks. The slopes are covered with overburden having variable thickness. Terrace deposits comprise of mixtures of clay, sandy silt, boulders and gravel in various proportions. These units include ABGM, RBGM, Terrace deposit and Moranic deposits. These units are mostly present in Aliabad, Karimabad, Nagar and Gojal Areas **(Vol-2, DWG1305 to 1324)**.

5.6.2 Rock units

The main rock units exposed in Project Area explored during neo-tectonic study are as follows:

IX. Granitic gneiss

X. Granodiorite

5.6.2.1 Granitic Gneiss

It is light grey to grey in color on fresh surface and weathers to light brown, coarse to very coarse grained, moderately to highly jointed, highly sheared up to higher elevation due to faulting, sparsely to moderately weathered, moderately hard to hard. It has well developed foliation with trending value N61ºW and plunging value 79ºNE. It is exposed at the right as well as at the left bank of the Hunza River. Some shear zones are also present with in the unit **(Vol-2, DWG-1305 to 1324)**.

On the basis of petrographic analysis, it is evident that the major constituents' minerals present in granitic gneiss are quartz, oligoclase, biotite while amphibole, chlorite, muscovite, epidote, and tourmaline are present as minor constituent minerals. The high percentage of quartz grains show strong strain extinction, indicating that this unit has Alkali Silica Reaction (ASR) potential. The rock may therefore not be used as a coarse aggregate with Ordinary Portland Cement (OPC) or High Alkali Cement. It may be used with low alkali cement, slag cement or cement with additives likes fly ash, pozzolan. Some chemical additives like lithium nitrate or silica fume can also be used to control this reaction. The Schmidt Hammer values ranges from **35** to **45**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

MPa indicating that rock is moderately strong to very strong. But in some shear zone where rock is tectonized locally, this value reduces up to **18-22 MPa**.

5.6.2.2 Granodiorite

It is dark grey to blackish grey in color, weathers to brownish grey, medium to coarse grained, moderately weathered, moderately hard to hard, moderately jointed intruded by pegmatite and granitic gneiss. It is foliated with trend and plunge values of N60ºW/79ºNE. Further downstream it becomes light grey to grey in color, coarse to very coarse grained. It is crushed, mylonized, and sheared at places. It is well exposed at both banks where it is intruded by many pegmatite dykes. Some shear zones are also present in this unit.

On the basis of petrographic analysis, it is evident that granodiorite is quite dominate in the Project Area. The major constituent's minerals present in this unit are plagioclase, quartz, biotite, and amphibole while Iron, muscovite, chlorite, and epidote are minor constituents. The high percentage of Quartz grains show strong strain extinction, indicating that this unit has ASR potential.

5.7 GEOLOGICAL STRUCTURES

As the Project Area has undergone multiple episodes of tectonics events, many regional as well as local faults and their splays have formed. Many thrust fault systems related to regional faults are present in the Project Area. There are many faults present in the vicinity of proposed ALHPP **(Vol-2, DWG 1305-1324)**. These faults are splays of MKT and Karakorum Strike Slip Fault, and lies in between these two fault systems. Some of these faults have been observed during surface geological mapping and marked on geological maps **(Vol-2, DWG-1305 to 1324)**. The brief description of these units are: -

5.7.1.1 Attabad-Hispar Valley Fault

It is thrust fault striking N30°E and dipping 40°SE, and is well exposed at the left side slope near the Project Area **(Vol-2, DWG-1305 to 1324)**. This fault crosses the Hunza River and forming a junction point with Hunza River and Attabad Fault in Attabad Village. The whole rock mostly granitic gneiss along its alignment is sheared / brecciated, forming fault breccia at many places. Due to high degree of shearing, many active slides have been originated along the slope. Rolling down of large boulder is quite common, and can be seen on old KKH. The retaining wall along this slide is fractured/jointed into parts due to operational stresses and downslope load movement. The ABGM along the slope is folded. It is clear indication that this fault has some movement, and is seismically active.

5.7.1.2 Attabad Fault

This thrust fault is striking N60°W and dipping 52°NE, exposed in area at rear side of Attabad Village. It is a small scale fault and terminates along junction point of three faults. A large brecciated and sheared rock is present along this thrust fault. At the junction point of these faults **(Vol-2, DWG-1305 to 1324)**, a large slide originated and destroyed about 2 Km of KKH. Sheared and brecciated rocks can be seen on outcrop at right side slope up to higher elevations in **(Vol-2, DWG-1305 to 1324)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5.7.1.3 Attabad River Fault

The exposure of this fault is present at right side slope of Hunza River. The breccia is well exposed at right side, just downstream of Sarat Suspension Bridge. The intensity of brecciation increases towards Salmanabad Village. In fact, Salmanabad Village was founded on this breccia. It may be present up to higher elevation **(Vol-2, DWG-1305 to 1324)**.

5.8 GEOLOGICAL & GEOTECHNICAL INVESTIGATIONS

5.9 SURFACE INVESTIGATIONS

The surface investigations / observations are one of the most important tools to reveal the geological conditions prevailing at the site. The natural processes operating on surface left clues to unfold the environments present in ancient time. During FS, surface geological mapping is carried out to record the geological conditions and to assess the deformation status of rock units exposed in the Project Area

5.9.1 Surface Geological Mapping

The surface geological mapping of the Project Area has been carried out on 16 Nos. topographic sheets prepared by Survey Division Peshawar, HP on scale 1:1000 with contour interval of 2m, with the help of Total Station, Plane Table and Brunton Compass in the field and presented at scale of 1:2000 **(**Photo 5.1**)**. The contacts between different rock units e.g. granitic gneiss and granodiorite as well as between different soil units have been marked. Structural features like joint sets, faults, foliation and shear zones along with dip and strike values have been marked on these sheets **(Vol-2, DWG-1305 to 1324)**. Four Nos. geological cross section were prepared along different alignments including, weir site, power tunnel intake area, and penstock alignment & powerhouse area.

Photo 5-1 Surface Geological Mapping

5.9.2 Neo-tectonics Study

During the FS, the understanding the Neo-tectonic setting operating under regional tectonic forces for the stability and planning of ALHPP has been studied in detail. The area under study has covered by the two Nos of GT sheets 42 L/15 and 42 L/11 at scale of 1:50,000, covering 40

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

km upstream and 50 km downstream of slided mass. These GT sheets were enlarged and printed at scale of 1:15000 and presented at scale of 1:30000, and used in field for alignment of local as well as regional faults **(Vol-2, DWG-1335 to 1337)**.

5.10 SUBSURFACE INVESTIGATIONS

Sub-surface geological and geotechnical investigation program was prepared to probe the sub-surface foundation conditions at weir site and its appurtenant structures including borehole drilling and test pits excavation. Drilling of exploratory bore holes was executed by Drilling Division, Hydroplaning, and supervised by Directorate of Geology, Hydro Planning WAPDA, Lahore.

5.10.1 Drilling

The main objective of drilling was to determine the nature and engineering characteristics of soil and rock units at Weir site and its appurtenant structures. It was performed to observe the subsurface geological conditions at depth in order to find out nature of the different strata in subsurface, to estimate the behavior and nature of overburden material, the depth of water table encountered. A total 06 bore holes with total drilling of 401m have carried out for subsurface exploration at different structures i,e Weir site, Sediment Flushing Channel (both at intake and outlet), Power tunnel alignment, Power house and tailrace area **(Vol-2, DWG-1330)**. The coordinates, structure, and depths of borehole are given in **Table 5-1**;

Table 5-1 Co-ordinates of Boreholes

Sr. No	Bore hole	Depth (m)	Northing	Easting	Elevation (m)	Location
1	BH-1	90	4018100.45	484075.46	2415.79	Weir site (Left abutment)
2	BH-2	60	4017996.26	484089.59	2452.81	Sediment Flushing Channel (Intake Area)
3	BH-3	61	4018061.58	483541.73	2456.92	Sediment Flushing Channel (outlet Area)
4	BH-4	80	4017721.34	482609.57	2445.37	Power Tunnel Alignment
5	BH-5	50	4017906.94	481690.72	2318.04	Power House area
6	BH-6	60	4017906.55	481605.02	2313.84	Power House area

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 5-2 Drilling Rig at BH-02 Sediment Flushing Channel

Permeability tests were performed using constant head method in overburden material at 3m interval whereas water pressure tests (Lugeon tests) in bed rock were performed at interval of 5m or at change of strata. Rock core and soil samples were collected from all the bore holes at various depths for lab testing. All the tests have been conducted at CMTL, WAPDA Lahore. The logs of drilled bore holes were prepared, Permeability values in overburden material and lugeon values in rocks were calculated and discussed structure wise and presented in **Volume 4B.**

The Standard Penetration Test (SPT) has been carried out in boreholes in overburden which mainly consists of Silty Sand with clay intercalations. The Cone Penetration Test (CPT) have been carried out in boreholes in gravelly Silty Sand with clay intercalations. CPT relied upon to provide information about the properties of soils / weak rocks. In foundation designs, SPT in overburden material, blow counts (N Values) are typically used to estimate nature and strength properties of soils to calculate the bearing capacity for foundation. The results are presented in bore hole logs **Volume 4 A**.

5.10.2 Test Pits

Ten test pits (3×3×3) m have been excavated in overburden material at weir site, slope along sediment flushing channel and power house area. Composite samples by con and quarter method from each test pit has been collected. Different tests have been conducted on these samples to estimate the engineering properties of the material.

To identify and proven source for coarse as well as fine aggregate, four test pits have excavated. Samples collected from these pits have been tested at CMTL, WAPDA, Lahore to check their suitability for fine as well as coarse aggregate. The logs of test pits have been prepared and presented in **Volume 4A.**

5.10.3 Laboratory Testing

Different rock core samples, to investigate the engineering properties of rock as well as soil (from test pits) at weir site, sediment flushing channel, power tunnel and powerhouse i have

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

been tested at CMTL, Lahore, to envisage their engineering properties and to check its suitability as construction material.

A total ten rock core samples from BH-04 (Power tunnel alignment) selected for evaluation of geotechnical engineering parameters for design purpose. The table below shows the testing program proposed in BH-04 at different depths.

Fifteen samples, i.e. 3 Block Samples and 3 samples from borrow area and 9 test pit samples have been selected for investigation. Samples from all tests pits have been selected by cone and quarter method and different test have been proposed to check their engineering properties and confirm their suitability as aggregate material.

All the laboratory tests on rock core samples were conducted in CMTL, WAPDA, Lahore. The detailed results are presented in laboratory testing **Volume 4B**.

5.11 GEOLOGY AND FOUNDATION EVALUATION

On the basis of surface geological mapping, geological x-sections, borehole logs, test pits excavation and laboratory test results, the foundation evaluation of various engineering structures proposed for ALHHPP have been made and described in the following sections: -

5.12 WEIR SITE

The surface geological mapping of the main weir area has been carried out at scale of 1:1000 with the help of Total Station, Plane Table and Brunton compass and presented at 1:2000. A geological X-section along line AA` has been developed and presented as drawing **(Vol-2, DWG-1326)**. The main purpose of geological x-section is to estimate condition prevailing in subsurface i.e. overburden thickness, extension / alignment of faults, extension / trend of rock units in the subsurface strata.

Photo 5-3 View of Weir Site.

An overtopping concrete weir founded on slided mass is proposed after foundation treatment. Geological rock units with which weir has to be abut, includes granodiorite, intruded by

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

pegmatite veins at right side. On left side weir has to be abut with ABGM formed by slided mass **(Vol-2, DWG-1309 & 1310)**. Some treatment / engineering solution have to be implemented for stability of the weir. A borehole BH-1, has been drilled at left side slope to investigate the subsurface geological conditions.

Table 5-2 Permeability Values in Soil and Rock

PERMEABILITY TEST IN OVERBURDEN		PERMEABILITY TEST (Lugeon) IN ROCK	
$<10^{-6}$	Impervious	0 to 5	Low Permeable
10^{-6} to 10^{-4}	Semi-pervious	5 to 15	Slightly Permeable
$>10^{-4}$	Pervious	15 to 25	Permeable
		>25	High Permeable

No rock has been encountered in this borehole up to 90m. The core recoveries CR (%) are graphically presented in **Figure 5-1.** The permeability test was conducted after every 3 meters, in most of test head could not be maintained due to cavities encounter in subsurface strata.

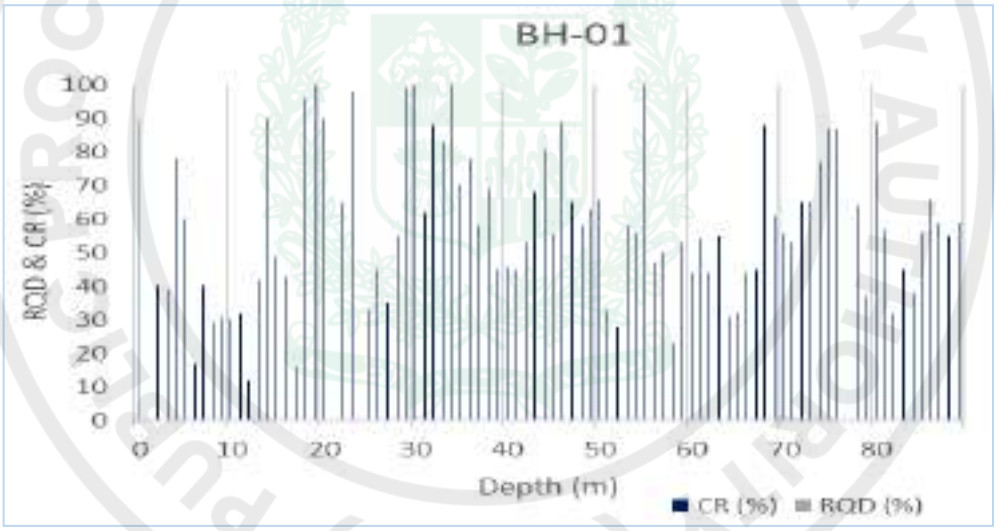

Figure 5-1 Graphical Representation of CR Vs Depth of BH-01.

It is noticed that head could not be maintained throughout the drilling of borehole. 100 % water loss has been observed throughout drilling activity. It indicates that slided mass is highly permeable with large cavities and open works as also testified by cementing job to stabilize the bore holes during drilling.

5.13 INTAKE AREA

The surface geological mapping of the intake area has been carried out at scale of 1:1000 and presented at 1:2000. A geological X-section along line BB` has been developed and presented as drawing **(Vol-2, DWG-1327)**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 5-4 Proposed Intake Area for Power Tunnel

The main purpose to develop geological x-section is to estimate condition prevailing in subsurface strata i.e. overburden thickness, extension/alignment of faults, and extension/trend of rock units. The intake area is proposed at the left side of the Hunza River. Granodiorite rock is exposed at steep angle where rock is hard, massive, strong to moderately strong with Schmidt hammer values ranges from 40 to 58 MPa **(Vol-2, DWG-1307&1310)**. The rock in foliated where platy minerals are aligned in specific orientation with trending at N42°W and plunging at 52°NE. Granodiorite is hard, strong to moderately strong, and sparsely to moderately jointed **(Photograph 5-4)**. But at higher elevation the rock is highly jointed and sheared, having vertical open joints which must be treated for stability and safety purpose.

5.14 POWER TUNNEL

It is observed during surface geological mapping that a fault is running obliquely across the alignment of power tunnel alignment **(Vol-2, DWG-1308,1309,1312,1315,1316 &1319).** A geological X-Section CC` has been developed to estimate the subsurface conditions and presented as **(Vol-2, DWG-1315).** The power tunnel has to be excavated mostly through the granodiorite with subordinate granitic gneiss at the left side slope of Hunza River. The strength of rock reduces downstream and near the termination point of slided mass, brecciated/ gaugic rock is present/exposed **(Vol-2, DWG-1315).** Rolling down of large boulders are quite common at this point. The rock units are quite crushed, sheared and brecciated forming active slides throughout its alignment.

A borehole BH-04 has been drilled to estimate the rock conditions in the subsurface strata. Lugeon test has been conducted in the field to check the permeability condition of the rock mass at every 5m interval. On the basis of data collected during borehole logging, a graph has been developed between depth Vs Rock Quality Designation (RQD) and Core Recovery(CR) and presented as **(Figure 5-2)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

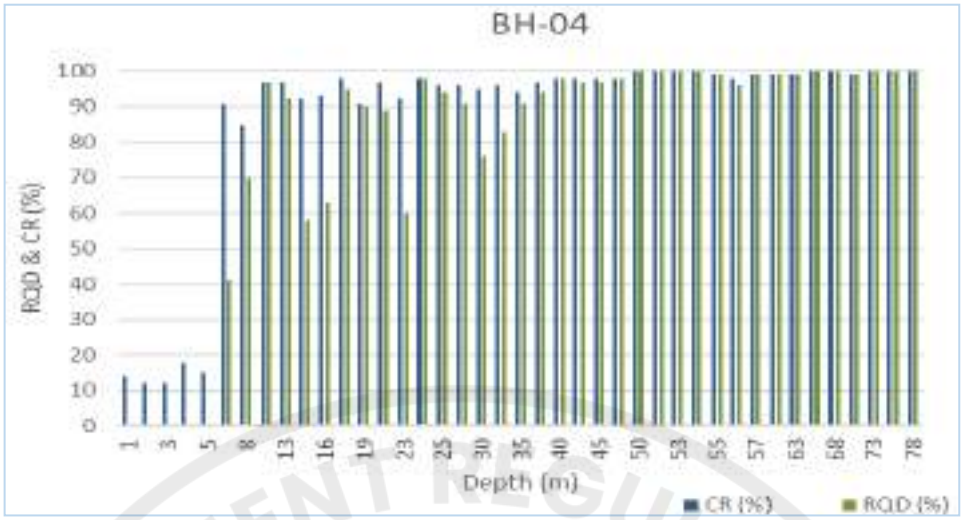

Figure 5-2 Graphical Representation of RQD&CR Vs Depth of BH-04.

During drilling work, it is estimated that the RQD values in upper 23m is moderately low after that the value increases/improved up to 100%. The lugeon values calculated after every 5m interval indicate that rock is low permeable. It shows that rock in sparsely jointed in subsurface. The lab test results indicate that RQD is quite high in lower portion but the strength index is moderate. The value of all test indicates that the rock in BH-04 is moderately hard and moderately strong with low cohesion “C” and low angle of internal friction “Ø”. While excavating through this portion, some treatment is required to enhance the stability of structure.

5.15 UNDER SLUICE SECTION/SEDIMENT FLUSHING CHANNEL

The surface geological mapping of the power tunnel alignment has been prepared at scale of 1:1000 in the field and presented at 1:2000. It is proposed at the left side of Hunza River **(Photograph 5-5)**. It is observed during surface geological mapping that the sediment flushing channel has to be excavated through ABGM of slided mass **(Vol-2, DWG-1309&1310)**.

Slided mass covers an area of about 1 Km and consists of huge volume of ABGM. One of the difficult and critical task is to stabilize the both side slopes along the sediment flushing channel. The large boulders of more than 25 m in length are present in slided mass. Benching in one of the best solution for such type of slope to stabilize. At some place, mashing or gabion may be helpful for slope stabilization/protection.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 5-5 Intake Area of Sediment Flushing Channel.

To investigate the nature of material exposed at left side slope, borehole BH-2 and BH-3 have been drilled at outlet and intake of sediment flushing channel respectively.

Permeability tests were performed at every 3m interval. It is noticed that throughout the borehole drilling, head could not be maintained and 100% water loss is observed during drilling.

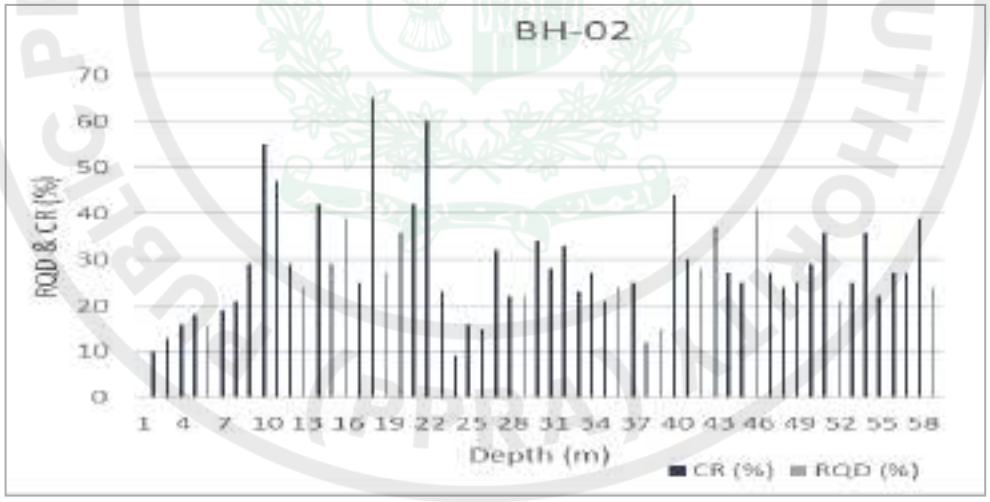

Figure 5-3 Graphical Representation of CR Vs Depth of BH-02.

On the basis of data collected during borehole logging, a graphs have been developed between depth Vs RQD and Core and presented as **Figure 5-3 & 5-4**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

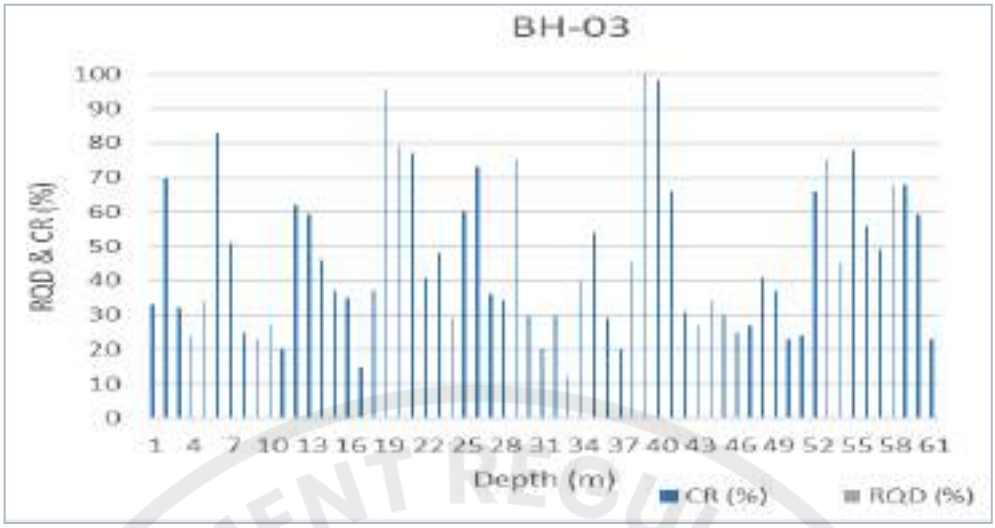

Figure 5-4 Graphical Representation of CR Vs Depth of BH-03.

Permeability tests have been performed at every 3m interval. These values indicate that the material is highly pervious.

It is clear from the drilling logs that rock is not encountered upto 60.0m in both boreholes. The drilling data and lab test results show that the boulders of overburden material ABGM) are hard and moderatly strong. The slope can be stablized by benching, but the permeability in BH-02 is quite high as head could not be maintained throughout drilling while in BH-03 is value shows that strata is pervious.

5.16 SURGE TANK AND PENSTOCK ALIGNMENT

It is proposed at the left side of Hunza River **(Photograph 5-6)**. It is observed during surface geological mapping that the granodiorite rock with granitic gneiss is exposed in surge tank area. It is moderately hard, sheared and highly jointed **(Vol-2, DWG-1319)**.

Photo 5-6 Proposed Area for Surge Tank.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

From surge tank 450m long penstock with diameter of 3.6m is proposed up to power house. Piers will support penstock alignment. The foundation of piers will be laid on overburden material **(Vol-2, DWG-1318 & 1321)**. The presence of clayey silt may create problem and might be removed prior to establish foundation for piers **(Photo 5-7)**.

Photo 5-7 Proposed Alignment of Penstock

5.17 POWER HOUSE

The surface geological mapping of the power tunnel alignment has been carried out at scale of 1:1000 and presented at 1:2000. It is proposed at the left side of Hunza River on a flat area **(Photo 5-8)**.

Photo 5-8 Proposed Power House Aarea.

It is observed during surface geological mapping that thick clayey silt has been deposited having depth of about 30 m as confirmed by drilling (BH-5 & BH-6). It is interbedded in upper

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

layers by RBGM while pure clayey silt is found in depth. It is deposited due to choking of Hunza River due to Salamanabad Slide **(Vol-2, DWG-1321).** A geological X-section DD` has been established to estimate the sub surface conditions and presented as **(Vol-2, DWG-1329).**

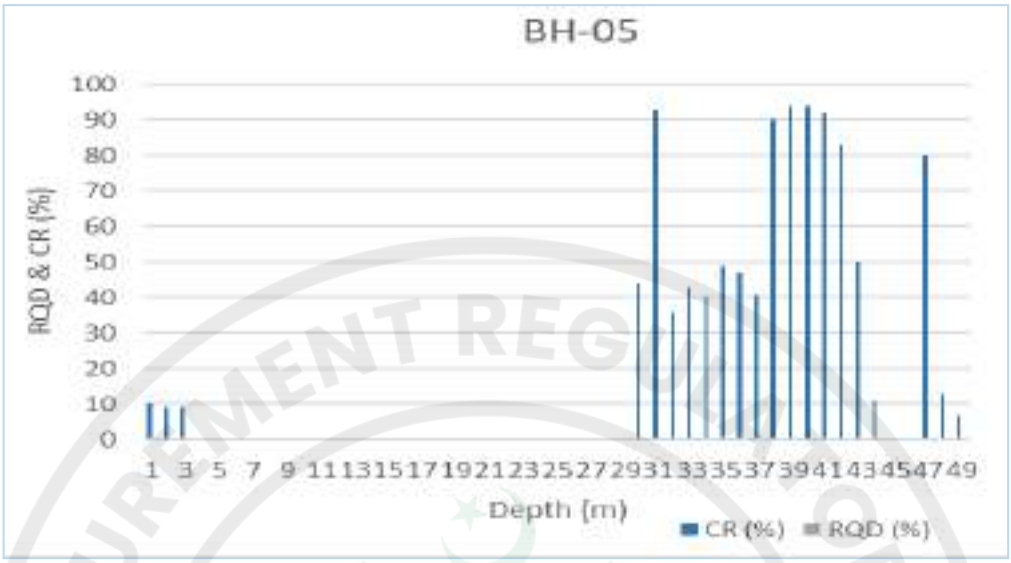

Figure 5-5 Graphical Representation of CR Vs Depth of BH-05.

To explore the nature of material present in subsurface, two boreholes, BH-05 and BH-06 with drilled depth of 50 m and 60 m respectively, have been drilled at powerhouse area. The summary of these boreholes is given in Figure 5-5 and 5-6.

On the basis of data collected during borehole logging, a graph has been developed between depth Vs CR and presented as **Figure 5-5**. Permeability tests have been performed. On the basis of data collected during borehole logging, a graph has been developed between depth Vs CR and presented as **Figure 5-6**. Permeability tests have been performed at every 3m interval

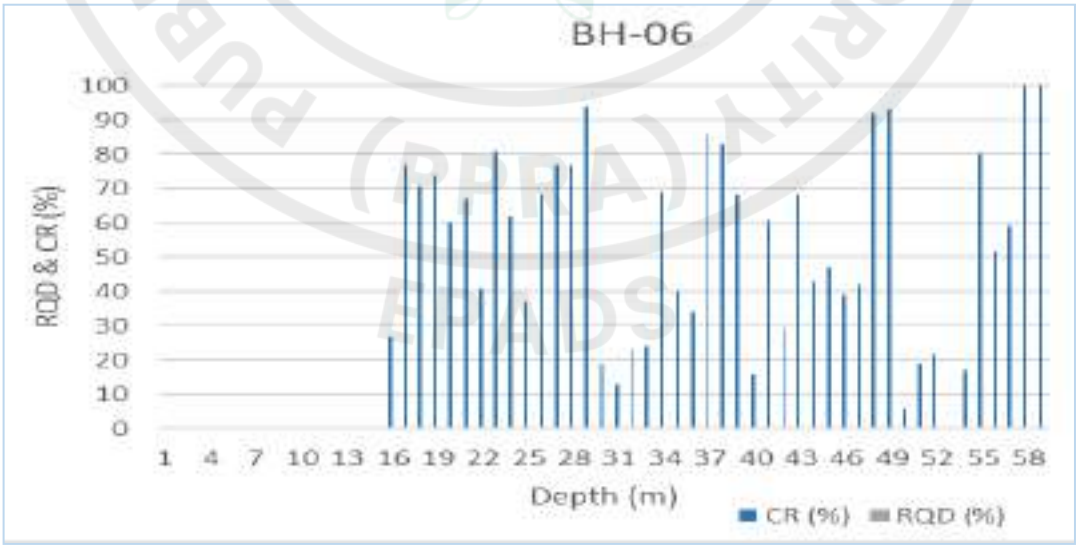

Figure 5-6 Graphical Representation of Depth Vs CR of BH-06.

It is clear from the drilling data that about 15 m and 30 m clayey silt have been encountered in BH-06 and BH-05 respectively. SPT have been conducted in the clayey silt for 18 inches'

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

penetration in these boreholes. It is estimated from this data that firm to stiff clayey silt is present. The permeability test conducted in this strata show that they have relatively high hydraulic conductivity. The lab test results indicate that the clayey silt has swelling potential.

Foundation of the powerhouse will be laying on overburden material. The whole thickness of clayey silt layer has to be removed/excavated prior to establish the foundation for power house.

5.18 TAILRACE CHANNEL

The surface geological mapping of tailrace channel has been carried out at scale of 1:2000. It is proposed at the left side of Hunza River. It is observed during surface geological mapping that the whole channel has to be excavated through the overburden material **(Vol-2, DWG-1321)**. Water after generating electricity will again fall into Hunza River near Sarat Village suspension bridge.

5.19 CONSTRUCTION MATERIAL

The rocks granodiorite and grantic Gneiss are exposed in/near the Project Area. Both are acidic rocks and cannot be used as coarse aggregate with Ordinary Portland Cement (OPC) due to Alkali Silica Reaction (ASR). Both rocks show deleterious quartz more than 5%. However, a huge outcrop of marble is exposed in/near Passu Village. More over ten test pits have been excavated for the study of aggregate material and foundation condition. These were excavated in river bed, slided mass and fine deposits near old Chinese Camp in power house area. Samples of marble has been collected from Passu Area to conduct laboratory testing in CMTL WAPDA, Lahore.

5.20 FINE AGGREGATE

Two types of fine aggregate sand and clayey silt have been selected for testing and proven source for fine aggregate. Samples were collected from 0 to 3 m depth (by coning and quartering method) for laboratory testing at CMTL, WAPDA, Lahore.

5.20.1 Sand Quarry

To fulfil the quantity of sand material during construction of ALHPP, ample quantity of this material is deposited in the tail area of Attabad Lake near Shishkat Bridge **(Photograph 5-9)**. A test pit TP-1 has been excavated, for sampling for lab testing. Log of test pit is given in **(Volume 4A)**. Gradation test indicates that 99% sand with only 1% silt and clay is present. The results of Accelerated Mortar Bar indicate minimum average expansion (0.039) for 28 days. Specific gravity and water absorption values also fall in permissible limits. The results of lab testing is provided in **Volume 4B.**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 5-9 Quarry Area Selected for Sand Near Shishkat Bridge.

The lab. test results show that it can favorably be used as sand quarry site during construction of ALHPP.

5.20.2 Silt and Clay Quarry

For fine aggregate (Clayey silt) three test pits 3x3x3m have been excavated to analyze the nature of material present in river bed. Two test pits TP-2 & TP-3 in Helipad/power house area and TP-10 near Klin area, near Ganesh Bridge, have been excavated to asertain the subsurface geological conditions prevailing in the area **(Photograph 5-10 & 11)**. Both composite as well as block samples from each test pit have been collected for lab testing.

Photo 5-10 TP-3, Excavated for Clayey Silt in P/H area.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 5-11 View of Clayey Silt in P/H area.

Lab test results indicate that the material consists of clayey silt with clay index ranges from 40- to 45%. Atterberg Limits and Swell Potential shows that some treatment may be needed prior to their use. Results of Modified Proctor Test on block and composite samples indicate that Max Dry Density (MDD) 1.7 to 1.8 mg/m^3 for clayey silt can be attained in range of 10 to 13% Optimum Moisture Contents (OMC). The laboratory test results can be seen in **Volume 4B**.

Another huge source of borrow area for silt and clay is present at brick kiln near Ganesh Bridge along KKH. It lies in economic haulage. A test pit TP-10 has been excavated in clayey silt and two block samples have been collected from this pit and sent to CMTL to conduct different tests. The log of test pit is presented in **Volume 4A.**

It indicates from lab test results that, clayey silt is present and can be used as fine aggregate material i.e. blanket material to minimize the seepage. The ratio of silt and clay naturally present in 60 and 40% respectively. It is present in adequate quantity in P/H area and near Ganesh Bridge.

5.21 COARSE AGGREGATE

The rock units exposed in the Project Area are acidic in nature on the basis of silica contents i.e. granodiorite and granitic gneiss. Due to sliding of huge mass down slope, large material is deposited in foothills which chocked the Hunza River. For coarse aggregate, three sites have been selected. Samples from slided mass, powerhouse area/river bed and Passu Area has been tested at CMTL, WAPDA, Lahore.

5.21.1 Passu Area

It is located about 35 km upstream of Attabad Lake along KKH near Passu Village **(Photo 5-12)**. Bulk samples have been tested at CMTL, WAPDA, Lahore. Petrographic analysis shows that marble is exposed. It consists of 97% of calcite, with specific gravity 2.84 and 0.37 water absorption, Los Angeles Abrasion has uniformity of wear 0.20, Crushing Value 24, with Flakiness Index of 22. Sulphate Soundness Test result has weight percent loss 0.89 **(Volume 4B)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 5-12 Exposure of Marble in Passu Village Area.

The laboratory test results indicate that the rock mostly consists of calcite with no ASR and no Alkali Carbonate Reaction (ACR). This material has no deleterious quartz, therefore it can be use with OPC. The values of tests results fall in permissible limit, therefore, it can be used as coarse aggregate for concrete with OPC.

5.21.2 Power House Area

Large quantity of RBGM is deposited near old Chinese Camp along old KKH route. Bulk sample from TP-2 has been tested at CMTL, WAPDA, Lahore. **(Photo 5-13)**.

Photo 5-13 View of RBGM in TP-2 at P/H Area.

It consists of marble, granite, granitic gneiss, with some slate pieces. As per lab. test results, material has specific gravity 2.78 with 0.33% water absorption. Los Angeles Abrasion value with uniformity of wear is 0.20, Crushing Value is 27, Flakiness Index is 21. Sulphate Soundness value is 0.81 and average expansion for 28 days in Accelerated Mortar Bar is 0.099, and Point Load Index is 4.15 MPa **(Volume 4B)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Petrographic analysis indicates that the rock is mostly granitic in composition and has more than 20% deleterious quartz, therefore, it cannot be used with OPC. To minimize the ASR, low alkali cement, cement with some additives like slag, fly ash, pozzolan can be used. Some chemical additives like lithium nitrate or silica fume can also be used. The finalization of the additive material depends upon the other strength and expansion tests during concrete mix design. Moreover, all the values of other tests fall in permissible limit, therefore, it can be used as coarse aggregate material for concrete with OPC by abiding the exceptions as described above.

5.21.3 Slided Mass

Sample from TP-7 have been collected to conduct different lab tests **(Photo 5-14)**.

Petrographic analysis shows that rock is granodiorite and has more than 20% deleterious quartz and cannot be used with OPC. Point Load Strength test result is 5.94 with diametrically failure, Specific Gravity 2.72 and Water Absorption 1.04%. Los Angeles Abrasion Test show 0.41 uniformity of wear, Crushing value 22 with Flakiness Index of 21. The value of Sulphate Soundness Test for this material is 1.87 **(Volume 4B)**.

Photo 5-14 View of Slided Mass in TP-6 at Left Side Slope of Hunza River.

Higher Los Angeles Abrasion, Sulphate Soundness and presence of deleterious quartz values, shows that this rock cannot be favored to be used as coarse aggregate material when compared with other two quarry sites. Thus this material is not recommended as coarse aggregate for concrete works.

5.22 BUILDING STONE

The granodiorite and granitic gneiss rocks are available in the Project periphery, for masonry works in sufficient quantities. Moreover, the large boulders, present in slided material can be used as rip rap material. To control the erosion/ wave action of water, this material has high strength UCS value ranges up to 72 MPa in TP-8. Similarly, the values of Property Index Test, Los Angeles Abrasion Test fall in permissible limits. The slided mass may therefore be used as rip rap material.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5.23 FILL MATERIAL

For protection works along slopes and structures, shoulder fill, construction of coffer dams, fill material of heterogeneous nature e.g. silty sand, sandy silt, gravelly sand etc. is available in river bed as well as in slided mass (**Photo 5-15**). This material is present in ample quantities in the economic haulage of the Project Area.

Photo 5-15 Fill Material (Boulder and Gravels) in Slided Mass.

The test pits excavated in the powerhouse area / river beds shows that large quantities of gravels and cobbles with subordinate sands are present. This material satisfy the quality test , therefore it can be used as fill material.

5.24 CEMENT AND STEEL

Cement and steel is required in adequate quantity for the construction of ALHH. The cement should be supplied from nearby cement factory. The most nearer unit of cement is situated in Haripur/WAH areas includes Askari Cement, Wah cantt unit with capacity of 3500 Ton/day; Fauji cement near Fateh Jang has two units one with 3500 ton/day and other with 6700 ton/day. It can be considered for the supply of cement

The steel has to be transported from Rawalpindi to fulfil the requirement of the Project. It is suggested that laboratory tests on representative samples should be carried out to determine the engineering characteristic of cement and steel prior to their use.

6 NEO TECTONICS AND SEISMIC HAZARD ANALSIS

6.1 GENERAL

A large slided mass move down and chock the Hunza River and KKH for more than 2km in January 2010 from right side near Attabad Village. This large slide causes a 25km long lake to develop upto Khyber Village in Gojal. Due to excavation and development of channel through this slided mass, the level of lake decreases down and extension reduces upto Shishkat Bridge. This large mass slided down due to some regional stress operating in this region. To understand these regional forces and their effect and vulnerability of expected slope material to slide, a Neo-tectonic study was conducted.

During the Feasibility Study, the colossal slide and as a result damping of Hunza River in 2010 has made the Neo-tectonic studies as core point. It is therefore, very important for the development of hydropower project in this area that understanding of Neo-tectonic setting should be explore to know the regional tectonic forces. Regional tectonic forces responsible for the massive slide, affecting project area severely as indicated by diverse features.

6.2 OBJECTIVES

Main objectives are:

- Evaluation of the regional tectonic setting of the area and recognition of fault (regional or local) which may act as a seismic source.
- Detailed investigation of the fault geometry, alignment, and structural deformations associated with these fault. These may include shear zones, fault bend folds, active slides and fault breccias.
- Recognition of active fault zones and their distinction from older, dormant fault zones.
- Assessment of the vulnerability of neo-tectonic activity along the fault/slides around the project area so that the movement along the affected area may be predicted.
- Identification of deformation/displacement in recent deposits to evaluate the activity of area.

6.3 METHODOLOGY

An array of activities including literature review, image analysis, field studies and data compilation is involved in Neo tectonic evaluation as per standard practices in Industry. These include:

- Collection of previous research on regional as well as on local geology, geomorphology and tectonics of project area.
- In-depth studies on satellite image analysis using GIS techniques by applying various image-enhancing techniques e.g. Digital Elevation Model (DEM) have studied, the lineaments and faults on regional as well as on local scale were recognized.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Detailed geological map of the project site, regional and local faults within the vicinity covering the upstream and downstream of the project area have been marked on GT sheets at scale of 1:15000 in the field area to understand the trend of regional tectonic forces.

- During field visit keen concentration has been given to characterize the kinematics of fault where possible e.g. sense of fault (Strike and Dip), alignment and type of fault, through and heave, dip direction and other associated characteristics.

- Development of fault-source map indicating various regional scale faults that may contribute seismic affect in the project area.

- The relationship of older tectonic features to the recent ones.

- Field evidences of Neo-tectonic features have captured in photographs including active slides, tiltness in recent deposits, folding, faulting, step fault, fault associated folding in recent deposits, topographic features including drainage pattern at slopes and abrupt shifting of river/stream course.

6.4 FIELD OBSERVATIONS

This study covers the 30 km upstream and 30km downstream of the project site covering the both banks of the Hunza River. Different features related to Neo-tectonics activity have been observed during site visit. In this study the focus was given to the recent deposits, at the both bank of river.

The main objective of the Neo-tectonic study was to identify/observe the feature of active tectonic events occurred in recent past about 0.1Million years ago. There are many field observations regarding the Neo-tectonic activity. Some of the Neotectonics features/observation are as under: -

- The tiltness in recent deposition, i.e. to study the slopes of gravels, clays, and sand layers w.r.t slope of the stream beds.

- Intersection of faults in recent deposits i.e. lacustrine deposits, terraces/ alluvial deposits or in any cultural features (houses, roads). The amount of displacement, Heave as well as Throw measurement, dip and strike of the fault.

- The presence of active slide zones.

- The displacement /uplift in fluvial as well as lacustrine deposits on each side of the lake/stream and magnitude of its displacement.

- Identify the zones of brittle as well as ductile deformation.

- To observe the movements along slicken sides / fault / joints blocks.

- The presence of hanging valley along the main streams

- The presence of escarpment slope along the plainer area

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- The presence of hanging valleys /cirques along main stream, in series and presence of waterfalls along it.

- Folding/bending in the recent deposits (alluvium, morainic, lacustrine).

The Neo-tectonic features at the right as well as left bank of Hunza River in different village from upstream to downstream **(Vol-2, DWG-1335 to 1337)** is described below: -

6.4.1 Passu Village:

Passu is one of the largest village in Gojal valley situated at the right bank of Hunza River along KKH about 35km from Attabad site. The great Passu Glacier, 56km in length is present near the village. Many deformational evidences were observed in recent deposits along the road.

- 2-3km Upstream of Passu village

N 4038610.325m

E 489292.583m

Ele. 2470.03m a s l

The coordinates measured by mobile topographer application.

A large deposit of RBGM material is present along the right side slope of the river along KKH. This material consists mostly of gravel, cobble, and pebbles with subordinate sandy material. Some inclinations in these deposits have been observed along roof and sole beds. This inclination varies from 15° to 35° layer-by-layer **(Photo 6-1).**

Photo 6-1 Inclined Gravel Layer under Effect of Shearing.

Some shearing effect has been chronicled along these planes in numeral layers. This shows that the area is tectonically active.

The clay deposit is overlain by morainic material of Batura Glacier. The clay deposits are tilted upward at an angle ranging from 10° - 15°. The area has undergone compressional regime, which uplifted the clay beds **(Photo 6-2)**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 6-2 Recumbent Fold Strata with Crenulation in Limbs in Clay Strata.

The clayey strata is folded with straight horizontal limbs and horizontal hingline. This shows that the horizontal compressional stress is applied on this material that turned this unit into folded strata **(Photo 6-3).** Many micro folds (crenulations) in both limbs of fold are present. The Hinge area toward outer layers are point out, that intense compressional stress is applied to the strata.

Photo 6-3 Stylolite/Pressure Solutions in Clay Strata.

The strata show some stylolite structures that are formed by expulsion of water through pressure solutioning. Alignment of wavelength and geometry of Hinge area indicates that the compressional stress is applied horizontally **(Photo 6-4)**. This shows that the recent stresses are functioning in this area.

Many joints are developed in the clay beds showing that there are relative movement in blocks along the plane, which might be act as micro faults **(Photo 6-5)**. The relative movement of hanging wall block moves down relative to the footwall block, signposted the development of Normal Fault.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

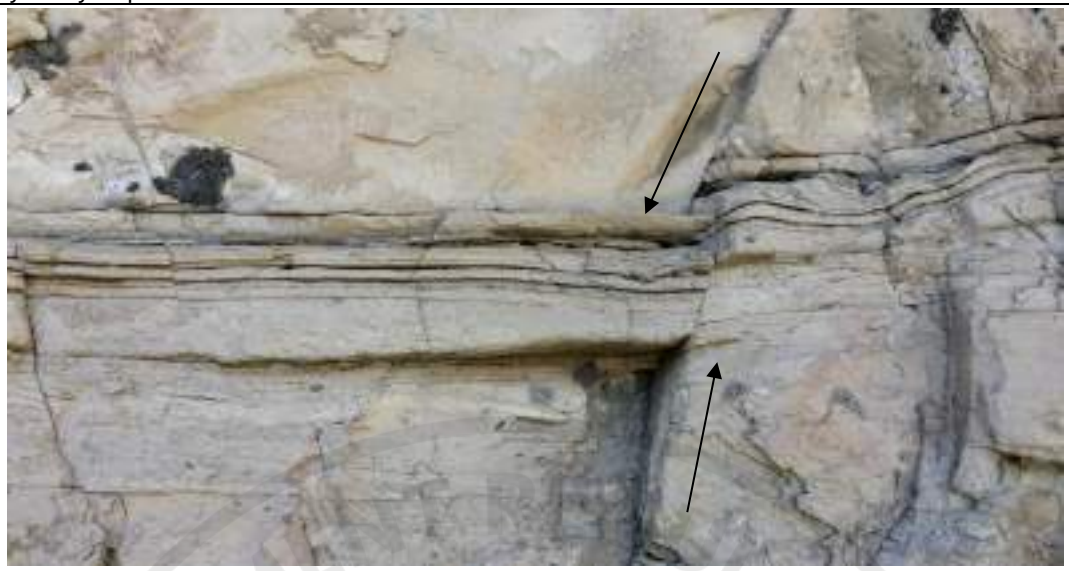

Photo 6-4 Micro Fault in Clay Beds.

At the same location there are cross cutting faults, dipping towards each other in clay beds. The block between two micro faults moves downward forming Graben structure while the block, that cannot move forming Horst structure **(Photo 6-5)**.

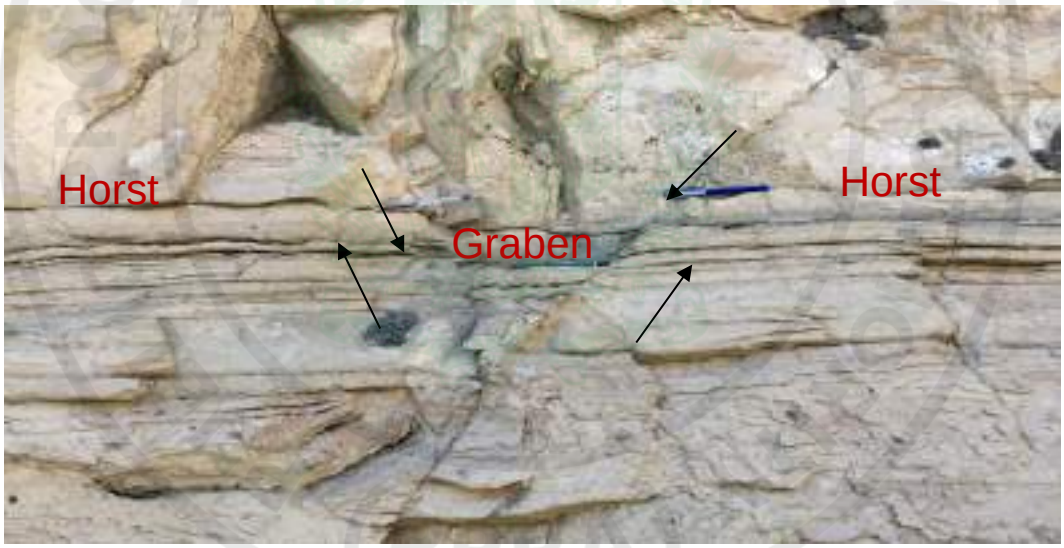

Photo 6-5 Horst and Graben Structure along Micro Fault in Clay Beds.

The formation of these structures in clay bed shows that there is relative movement along the micro faults in recent deposits.

The development of these Normal Faulting system in such compressional regime indicates that these deposits are under such environment where two thrust faults dipping toward each other are present. The upthrown block between these two faults undergone extensional regime where normal faults are developed. This indicates that this area is under active tectonics regime.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

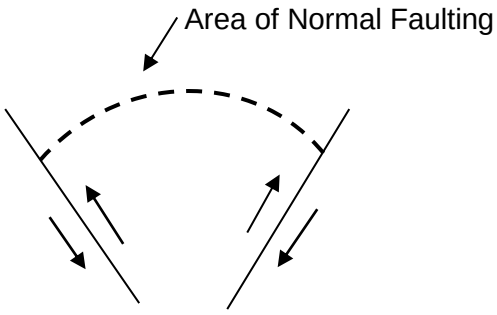

Figure 6-1 Development of Normal Faults under compressional regime.

6.4.2 Road section from Murradabad to Hussani Village:

Coordinate

N 4033080.557m

E 489417.275m

Ele. 2656.69 m a s l

Just upstream of Hussani village a large mass of ABGM and Brecciated rock is exposed along the road. It is present in the alignment of thrust fault where crushed marble is in contact with Passu Slates. The faulted contact between slate and marble is well exposed along road **(Photo 6-6)**.

Photo 6-6 View of Brecciated Rock Upstream of Passu Village.

In this area two faults are intersecting each other, one is striking N60°E and dipping 40°NW while other is striking NW and dipping NE **(Vol-2, DWG-1335)**. Due to these faults discrete hillocks have formed with thin overburden overlain by fault breccia. At few feet away from breccia, a slided material consist of ABGM is present along road. Apparently this material seems to be stable but in excavated portion, this material is folded. Compressional forces are responsible for this deformation exposed at slope **(Photo 6-7)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 6-7 View of Folded ABGM Just Upstream of Passu Village.

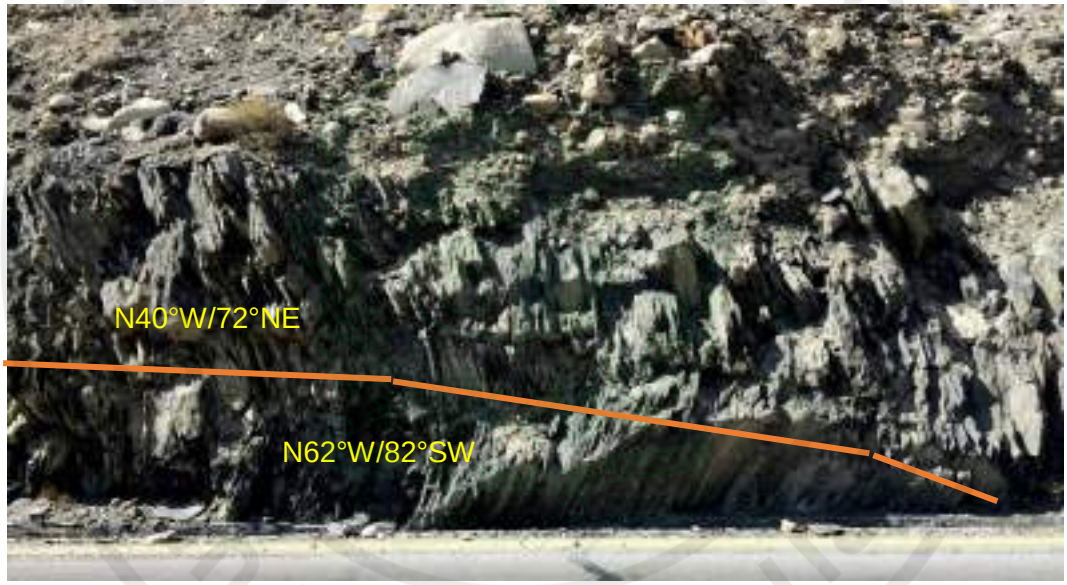

Photo 6-8 Change of Dip along Shear joint.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Rock (Passu Slates) is locally folded, some shear joints along which the cleavage plane (originally bedding planes) across shear joint has different dip values. The overall strike of slates is NW and Dipping in NE. but along this shear joint some movement took place and the value of dip changes from SW to NE **(Photo 6-8)**. Change of sense of dip along the shear joint shows that some shear forces are active in the area. The development of such joints indicate the brittle deformational style.

6.4.3 At Sarat Village:

Coordinates:

N 4018254.850m

E 481549.816m

Ele. 2371.35m a s l

Due to Salmanabad slide in 1858, a large lake developed in upstream reaches. The depositional clayey silt can be seen on both bank of Hunza River. Due to operational neo-tectonic forces, deformation including folding, jointing, micro faulting has been developed in these deposits.

Both vertical and oblique joints can be seen in clayey silt at right side near Sarat suspension bridge. The strike and dip values of vertical and oblique joints are N38°W/87°NE and N32°E/63°SE respectively **(Photo 6-9)**.

Photo 6-9 View of Vertical and Oblique Joints in Clayey Silt at Sarat Village.

Clayey silt beds are striking N 80°E and dipping 18°NW at the left side of road to Sarat Village while at the right side of the road these beds have strike N 32°E and dipping 9°SE **(Photo 6-10 & 6-11)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 6-10 Tiltness in Clayey Silt Beds, Left Side of Road at Sarat Village.

The strike of the beds is NE while the dip is in opposite direction, indicating that it forms some sort of antiform. Formation of antiform in recent deposits clearly indicates that lateral shear compressional force are operational in this area.

Photo 6-11 Tiltness in Clayey Silt Beds, Right Side of Road at Sarat Village.

Just downstream of Sarat village near the suspension Bridge, fault breccia is exposed along the river showing the alignment of fault.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 6-12 Folded and Sheared Clayey Silt at Sarat Village.

Photo 6-13 Sheared and Smeared Clayey Silt at Sarat Village.

Photo 6-14 Fault Breccia just D/S of Suspension Bridge at Sarat Village.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Folding, jointing, smearing and shearing of clayey silt **(Photo 6-12, 6-13, 6-14)** deposit shows some lateral stresses are actively operating in this area. The active slides and rolling down of brecciated material from this slope indicate that it is tectonically active area.

6.4.4 Inside Tunnel 2:

Many cracks/joint are going to develop in the concrete specially in crown area in tunnel-2. The pattern of the cracks indicates stress release and shear oblique joints **(Photo 6-15)**.

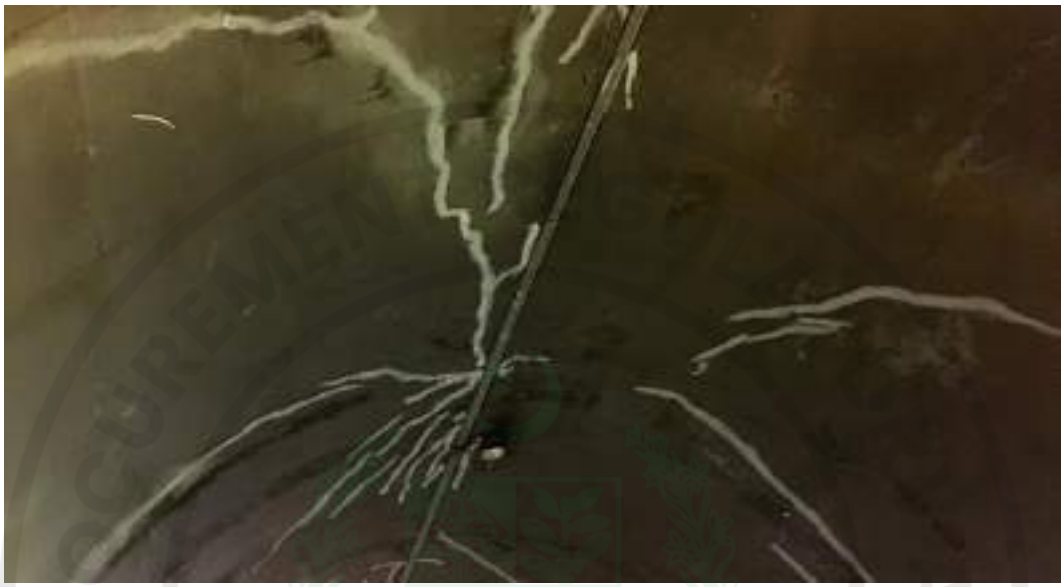

Photo 6-15 View of Recently Generated Joints Tunnel-2.

As per geological conditions concerns, this portion of tunnel in is under influence of two faults **(Vol-2, DWG-1336)**. Rock is highly crushed, rolling down of boulders is quite common along these active faults. The active tectonic forces are responsible for the development of fractures in this terrane. The same features are also being noted in concrete area in between tunnel 2 and 3 **(Photo 6-16)**.

Photo 6-16 View of Recently Generated Joints Between Tunnel-2 & 3.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The concrete slab fractured between tunnel 2 and 3. It is evident that some tectonic forces are recently operative in this area.

6.4.5 Power House area:

In powerhouse area near helipad along old KKH, clayey silt is present where Chinese camp was established. The clayey silt was deposited after river choking due to Salmanabad slide.

Photo 6-17 Micro thrust fault in clayey silt beds near helipad.

Due to operational compressional stresses, some deformations including faulting, shearing, folding, and tiltness in clayey silt have been observed. The relative movement of both blocks against fault plane indicates compressional environment, moves the hanging wall block upward **(Photo 6-17)**.

Photo 6-18 Inclination of Clayey Silt near Helipad.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The clayey Silt beds are well exposed at the left side of Hunza river near Sarat bridge. The clayey silt beds are well jointed and tilted upward at an angle ranging from 10° to 15° **(Photograph 6-18)**. The inclination of the beds is in recent soil is active tectonic feature.

Near old Chinese camp, at powerhouse area, the clayey silt is folded **(Photograph 6-19)**. Folding in recently deposited clayey silt may result of slipping along fault plane under regional compressional shear force, results in the formation of folding and faulting.

Photo 6-19 Folding in Clayey Silt near Helipad/Power House Area.

Near the SCO building, along old KKH, near tunnel-1, some cracks are going to develop in recently deposited material. The development of joints is mostly parallel in nature but occasional cross cutting joints also present **(Photo 6-20)**.

Photo 6-20 Development of Parallel Joints near SCO Building.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6.4.6 At Murtazabad- Shahyar Road:

Coordinates:

N	4016299.113m
E	465418.47m
Ele.	2095m a s l

Just crossing the Murtazabad to Shahyar bridge, a thick alluvial deposit consists of gravels, cobbles, pebbles interbedded with silty sand is exposed. This material moves upward against fault plane and form fault bend fold **(Photo 6-21)**.

Photo 6-21 Inclination in Clay Silt and Gravels.

The beds are tilted at an angle of 22° to 30°. Many micro fault in sand beds have been observed in hinge area of the fold. The ramp and flat geometry having NE striking and Dipping SE **(Photo 6-22)**.

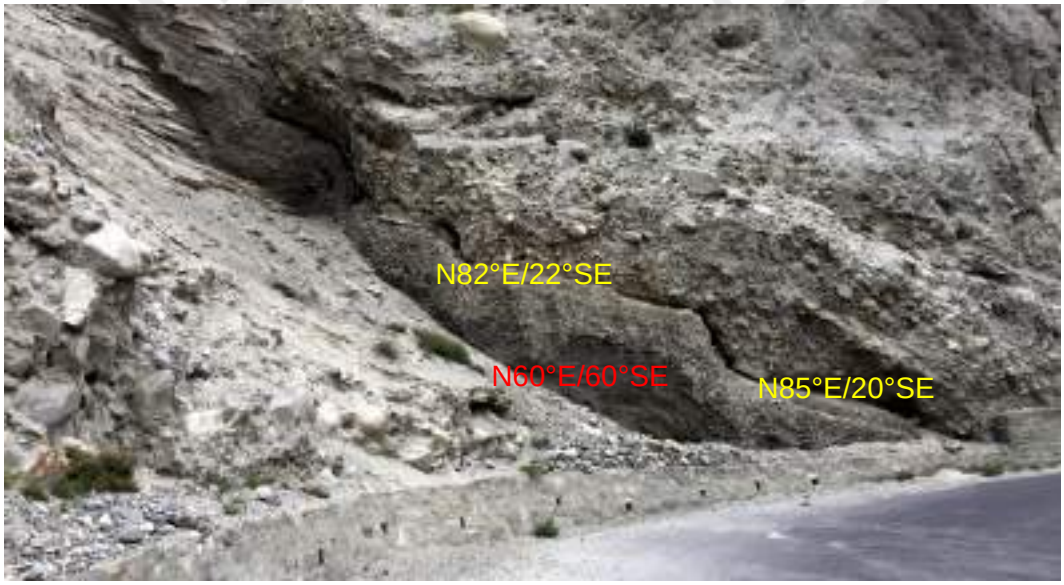

Photo 6-22 Ramp and Flat Geometry along Fault.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Some micro faults have been observed in this alluvium. Step faulting on micro level is well preserved in sandy material **(Photo 6-23)**. This alluvium is overlain by morainic material; same joint pattern is going to be develop in it. Some open joints ranging from 10cm to 150cm have been observed there. All these features indicate that the tectonic forces are active in this area.

Photo 6-23 Development of Micro Faults in Sand.

6.4.7 In Tashot Village:

Coordinates:

N	4012830.531m
E	462157.244m
Ele.	2111.0ma s l

After crossing suspension bridge near Tashot Bridge, a thick deposit of RBGM and Clayey silt is exposed along the road toward Phakhar village. Due to some recent activity, clayey silt is displace and smeared along micro fault.

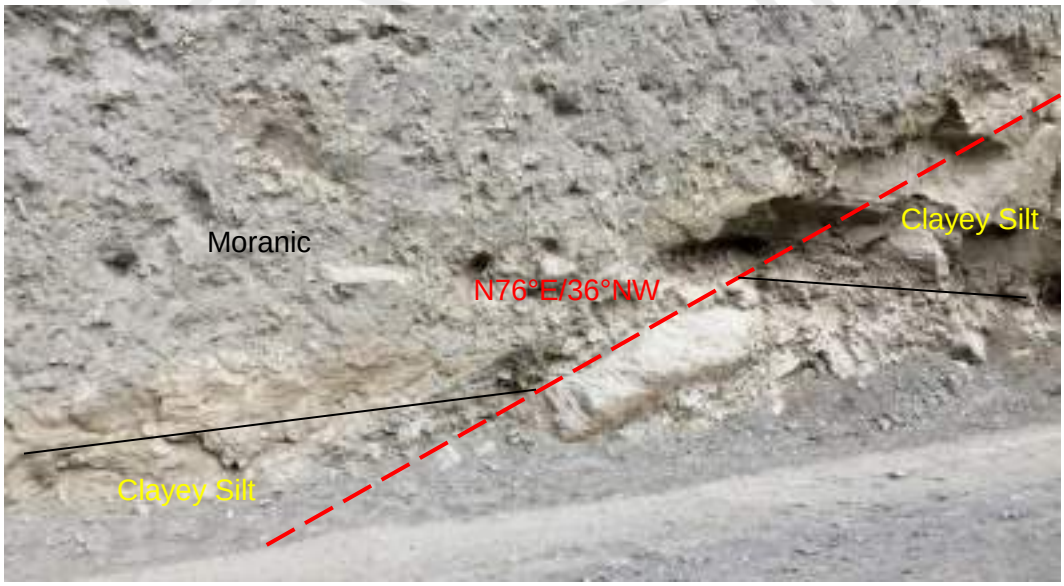

Photo 6-24 Development of Micro Faults in Clayey Silt.

Upward inclination of 6°in recent RBGM in measured along the road **(Photo 6-24, 6-25)**.

Photo 6-25 Inclination in RBGM in Tashot Village along Road.

6.5 SEISMIC HAZARD ANALYSIS

The quantitative and qualitative seismic hazard analyses presented in this study were preceded by a detailed appraisal of the structure, geodynamics and neotectonics, to characterize the on-site and regional tectonic scenario to assist in proposing a suitable earthquake resistant design. This study has used the seismic source characterization deduced in the accompanying Neotectonic studies and calculated the earthquake potential hazard and related ground motions as presented in this report.

6.5.1 Probabilistic Hazard Analysis

Both PSHA and DSHA were carried out using EZ-FRISK software Version 7.65 developed by Risk Engineering Inc. USA. The latest version of R-CRISIS Software version 21.1.1 developed by PEER, USA was also used during the current study. The purpose of using both software was to cross check the validation comparing the quality of the seismic hazard analysis of the two software for the project. During the study it was found that Ez-Frisk software is more standardized as compared to R-CRISIS software in quality of analysis as well as the smart outputs of the analyzed results. Therefore, Ez-Frisk software has been preferred and used in the in the final analysis.

Important input parameters for different seismic zones used in probabilistic approach are presented in **Table 6-1**. It is assumed that weir/dam foundation will mainly be placed on gravelly soil (alluvium) therefore the site condition was taken as gravelly soil with average shear wave velocity at 30 meters' depth (V_{s30}) of 450 m/sec for soil site (alluvium) and 760 m/s for rock sites. The mean total hazard curve was obtained by giving equal weighting to all the Five NGA W2 Ground Motion Prediction Equations.

The total hazard curve obtained for the project area is shown as **Figure 6-2** and the total mean Hazard Spectra showing combination of all used Ground Motion Prediction Equations for Attabad HPP is presented as **Figure 6-3**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 6-1 Seismic Source Parameters for Probabilistic Analysis

Source Zone	Seismic Source Zone	Min. Magnitude Mw	Activity Rate / Year	β	Max. Magnitude Mw
1	Karakorum	4.0	1.929	1.120	7.3
2	Nanga Parbat	4.2	1.112	1.101	7.0
3	Western Himayan	4.1	5.339	1.44	7.0
4	Hindukush	4.2	59.107	1.20	8.0
5	Kashmir Himalaya	4.2	7.143	1.13	7.8
6	Kohistan	4.1	10.500	1.07	7.5

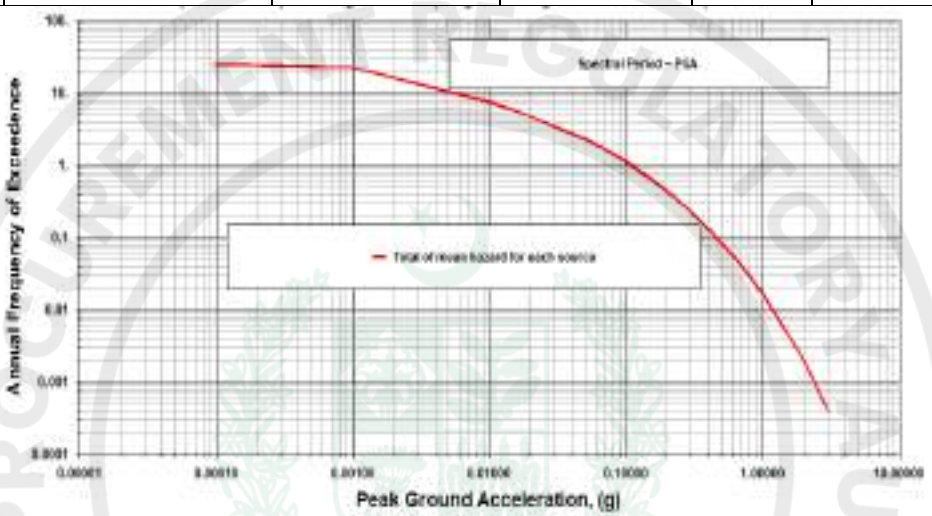

Figure 6-2 Total Hazard Curve for Attabad HPP

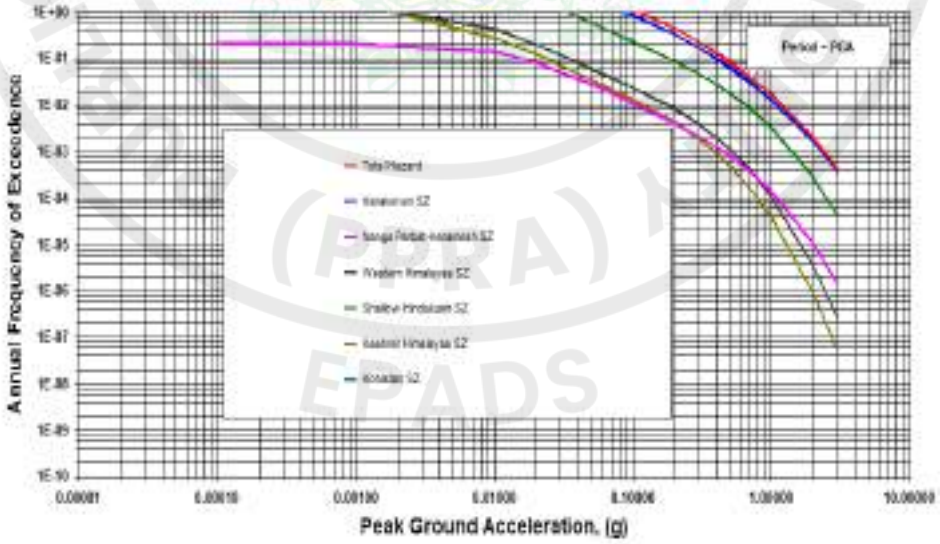

Figure 6-3 Earthquake Hazard by Seismic Sources, showing spectral response.

6.6 DETERMINISTIC SEISMIC HAZARD ANALYSIS (DSHA)

The capability of the faults to generate earthquakes is ascertained by means of analysis of historical and instrumental seismic data and geological criteria such as rupture length – magnitude relationship or fault movement – magnitude relationship.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The main tectonic features around the project site within a radius of 200 km which could be controlling the maximum earthquake hazard are as follows:

- Hunza Fault
- Main Karakoram Thrust (MKT)
- Main Mantle Thrust

Empirical correlations have been developed between maximum potential of a fault and key fault parameters like rupture length, fault area, fault displacement and slip rate. Out of these fault parameters, only fault lengths are known with sufficient accuracy. For the faults around the Attabad Lake hydropower project site, the half rupture length of the faults has been taken for determination of maximum potential magnitude. The maximum earthquake magnitude (in moment magnitude M_W) of each of the fault was calculated using Wells & Coppersmith (1994) relationship between fault rupture length and magnitude and the input data given in **Table 6-2** has been used for deterministic approach.

Table 6-2 The Controlling Faults with Quantitative Features (input values of DSHA)

Controlling Faults	Fault Type	Fault Rupture Length (km)	Distance (km)	Maximum magnitude potential	
				Catalogue data	Conservatively Assigned
Hunza Fault	Thrust	5 inferred	1.4	6.1	6.7
MKT	Thrust	200	32	7.0	7.6
MMT	Thrust	260	71.69	6.9	7.6

Ground motion prediction equations developed under the Next Generation Attenuation (NGA) West 2 Project of PEER (Pacific Earthquake Engineering Research Center, University of California at Berkeley, USA) are used to obtain the median and median plus-one percentile levels of peak horizontal ground acceleration (PGA) in deterministic approach.

The NGA equations are developed using a large worldwide database of strong motion recording of earthquakes of magnitude 4-8 and distances ranging from 0-200 km in accordance with ICOLD Guidelines. The NGA equations are preferable over the older equations for the evaluation of seismic hazard particularly in the near field as these are based on a broad spectrum of data recorded in the near field. The same attenuation equations were used for the PSHA approach too.

For all the seismic sources, thrust rupture mechanism has been considered. It is assumed that dam foundation will mainly be placed on gravelly soil therefore the site condition for dam/weir was taken as gravelly soil with average shear wave velocity for top 30 meters (V_{s30}) of 760 m/sec. The depth to basement rocks (Z_{25}) is taken as 5 km. The Peak Horizontal Ground Acceleration (PGA) g values have been calculated using the latest Five sets of NGA West 2 Ground Motion Prediction Equations (GMPEs).

Input values in DSHA are given in **Table 6-2**. The analyzed results obtained through DSHA (Deterministic Seismic Hazard Analysis) are presented in Figures.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6.7 DETERMINISTIC RESPONSE SPECTRA

Deterministic response spectra for SEE at 50th percentile and 84th percentile levels over the Five NGA West 2 equations are shown in **Figure 6-4 & 6-5** respectively.

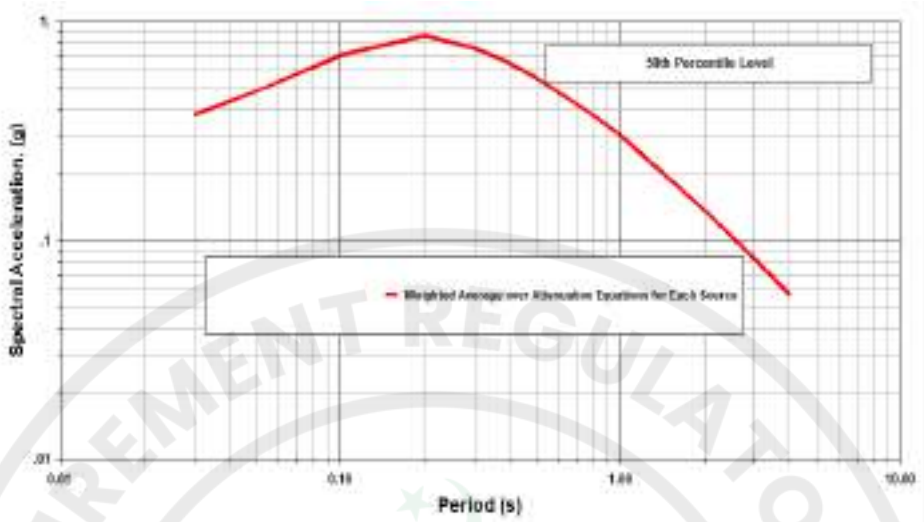

Figure 6-4 Deterministic Spectra at 50th percentile level weighted average

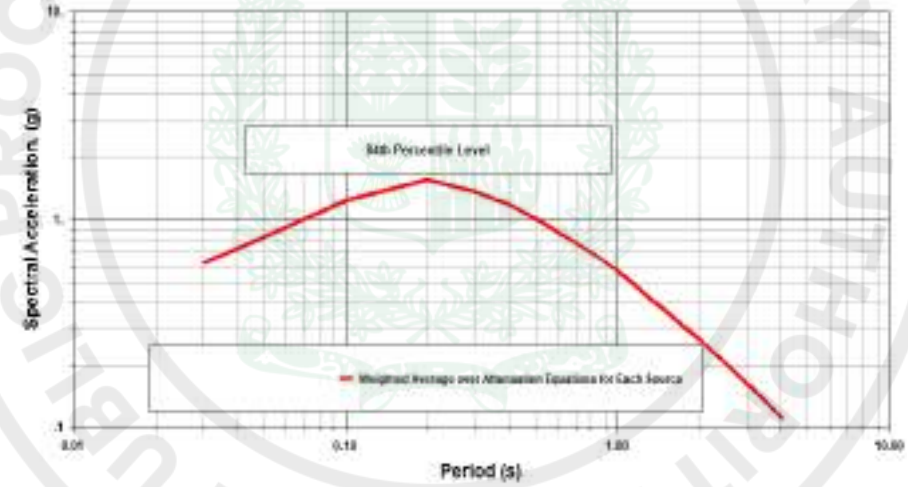

Figure 6-5 Deterministic Spectra at 84th percentile.

6.7.1 Deterministic Pseudo Spectral Acceleration (PSA)

Pseudo spectral acceleration has been worked out using the latest version of R-CRISIS software. Pseudo spectral acceleration Vs time is given in **Figure 6-6**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

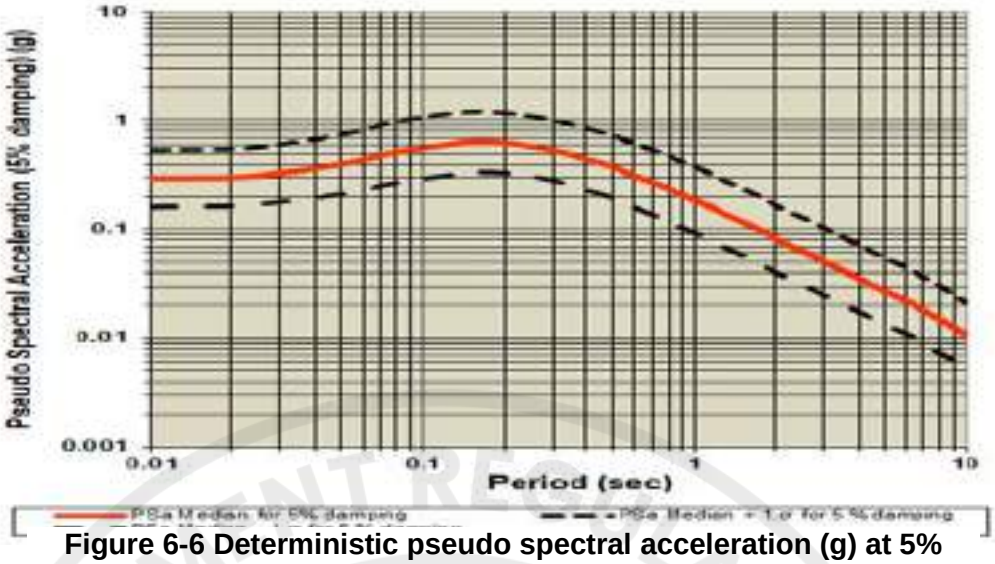

Figure 6-6 Deterministic pseudo spectral acceleration (g) at 5% Damping.

6.8 SELECTION OF SEISMIC DESIGN PARAMETERS

6.8.1 Safety Evaluation Earthquake (SEE)

As per ICOLD guidelines (2016) the Safety Evaluation Earthquake (SEE) will produce the maximum level of ground motion for which the dam should be designed or analyzed. For dams whose failure would present a great social hazard, the SEE will normally be characterized by a level of motion equal to that expected at the dam site from the occurrence of deterministically evaluated MCE or of the probabilistically-evaluated SEE earthquake ground motion with a very long return period, for example 10,000 years for high consequence large dams. Depending on the circumstances (e.g. the importance of the dam, the consequences of a dam failure, it is recommended to design safety-critical elements such as the bottom outlet and/or spillway gates for the SEE. It will be required at least that there is no uncontrolled release of water when the dam is subjected to the seismic load imposed by the SEE.

As per the latest ICOLD Guidelines, for medium consequence dams, median value (50th percentile level) is recommended whereas for high consequence dams, the SEE ground motion parameters should be estimated at median plus one (84th percentile level) if developed by a deterministic approach and need not have a mean annual exceedance probability (AEP) smaller than 1/10,000 if developed by a probabilistic approach. For a particular project of importance such as hydropower project, optimum percentile level may be any optimum percentile level between 50th percentile level to 95th percentile level. For Attabad Lake HPP, 66th percentile level has been worked out and the same is recommended.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

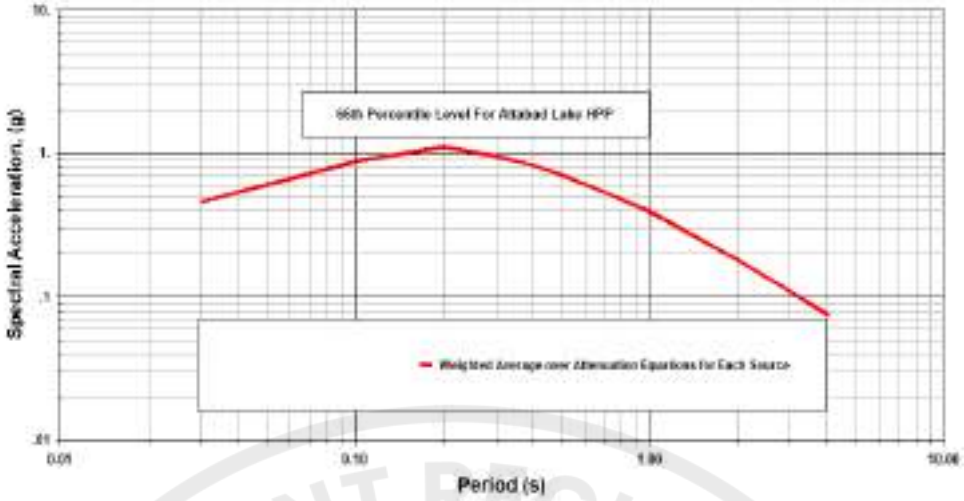

Figure 6-7 Deterministic Spectra at 66th percentile level of SEE.

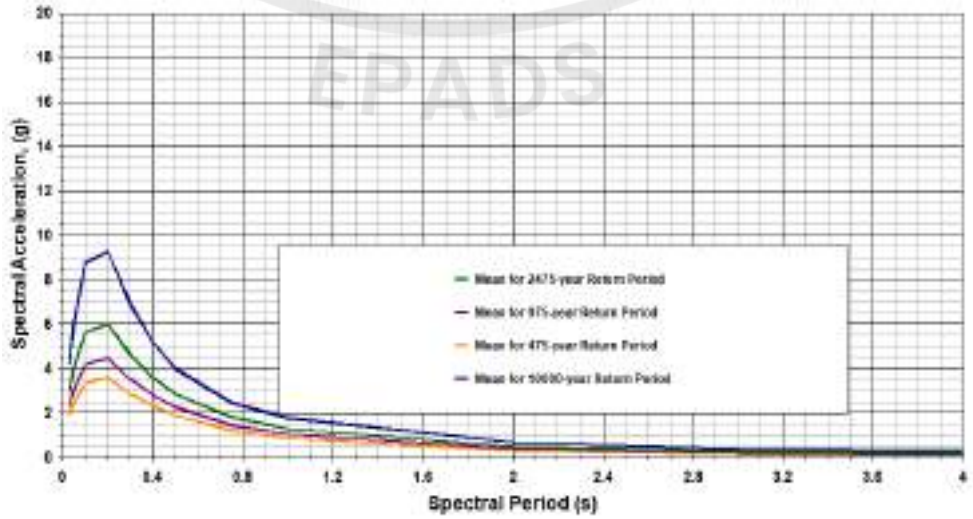
6.8.2 Operating Basis Earthquake (OBE)



The Operating Basis Earthquake (OBE) represents the level of ground motion at the dam site at which only minor damage is acceptable. In theory the OBE can be determined from an economic analysis, but this is not always feasible and, in many cases, it will be appropriate to choose a return period of about 145 years (i.e. a 50 % probability of not being exceeded in 100 years). The dam, appurtenant structures and equipment should remain functional and damage easily repairable, from the occurrence of earthquake shaking not exceeding the OBE.

Since the consequences of exceeding the OBE are normally economic, the circumstances in a particular case may justify use of a more severe or less severe event for the OBE. The resulting return period depends on prevailing conditions.

Because of the above definition, the OBE is the best determined by using probabilistic procedure. OBE ground motions are significantly lower than those for SEE.

6.8.3 Uniform Hazard Spectra (UHS)

Uniform hazard spectra for Attabad Lake Hydropower Project for OBE (145 year return period), DBE (475 year and 2475 years return period) and SEE (10,000-years return period) are presented as **Figure 6-8.**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Figure 6-8 Uniform Hazard Spectra (UHS) showing mean hazard for various return periods.

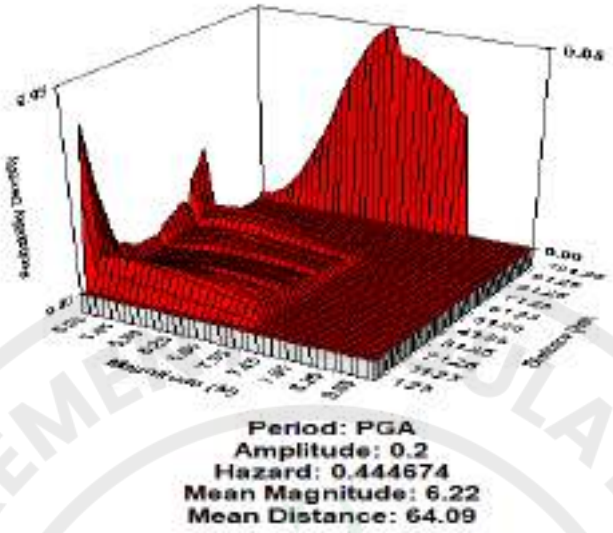


Figure 6-9 Deaggregation of Mean Hazard, Mean Magnitude and Mean Distance.

6.9 RESULTS

Based on the analysis results, the following earthquakes design parameters are concluded and recommended for Attabad Lake Hydropower project.

Operation Basis Earthquakes (OBE):

OBE at return period of 145 years is recommended as follows:

OBE Horizontal = 0.24 g

OBE Vertical = 0.17 g

Safety Evaluation Earthquakes (SEE):

For the design of dam / weir, the following PGA 'g' values for SEE (Safety Evaluation Earthquakes) are recommended:

SEE Horizontal = 0.44g

SEE Vertical = 0.29g

For the design of appurtinent structures including spillway gate betc. the following PGA 'g' values for SEE (Safety Evaluation Earthquakes) are recommended:

SEE Horizontal = 0.38g

SEE Vertical = 0.26

7 PROJECT LAYOUT

7.1 GENERAL

Attabad Lake Hydropower Project (ALHPP) has been identified on Hunza River downstream of Attabad Lake due to creation of dam because of land slide from right bank of Hunza River in January, 2010, 20 km upstream of Aliabad, Hunza Valley, Gilgit-Baltistan. ALHPP is proposed on Attabad Lake. Attabad Lake is about 15 km upstream of Ganish Bridge and about 111 km upstream from Gilgit.

The Dam due to landslide created a Lake behind it at Attabad not only possess a threat but at the same time an opportunity for making use of the head due to this Earthen Dam. Due to lake formation, there is potential drop of more than 100 m in 2.5 km river reach. The mean annual flow of Hunza River at Attabad Lake is 204 m^3/s. The Project Layout is to be configured considering the power demand and demand pattern of regional grid. Attabad Lake storage can be used for daily peaking. A design discharge with peaking storage facility is to be selected to generate the installed capacity 95% time of the year in peak hours. From the available flow data and estimated flow series at Project Area, a discharge of 60 m^3/s has been taken as design discharge.

The Project Layout options are to be studied with due consideration of topographic and geological features of the Area. In the Project Layout configuration, the existing natural dam treated will be used as diversion structure. The present river width has been narrowed due to land slide downstream of lake. The river width in the slided area is to be increased with proper control structure for design flood. In addition, sediment flushing arrangement is to be provided, so that a live storage of lake could be maintained. The water conveyance channel from reservoir to powerhouse is to be made that is technically sound and economical option. Considering the topography and geological features, surface powerhouse is viable at a site, 2.5 km downstream of the Lake. Alternative Project Layout are considered to arrive at the better option both technically and economically.

In this section, alternative Project Layouts have been discussed based on the investigations and studies. The selection of Project Layout has been made on the basis of technical soundness and economic viability.

7.2 ALTERNATIVE PROJECT LAYOUT

The Project layout has been considered on either bank with powerhouse near Attabad. Options for structures' location are limited due to land slided area, steep slope in reservoir area, and weak geological formation in the Project Area.

7.2.1 Alternative-I: Project Layout on the Left Bank

The left bank has been examined in detail to propose Project Layout with power intake, 2.3 km low pressure headrace tunnel, surge tank, embedded penstock and surface powerhouse near Hunza river, 2.5 km downstream of Attabad Lake.

The main access road to Project Area from down country is KKH passes on the left bank in Project Area leading to Chinese Boarder through Khunjerab Pass. After land slide, about 7 km highways tunnel has been constructed on the left bank because about 19 km was submerged

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

in the lake. The access to the area and for construction activities, the left bank is the suitable bank to propose the Project Layout. Since the slide did not initiate from left bank the slopes are more stable. The geological conditions favour intake, headrace tunnel and surface powerhouse. The slided area of about 500 m is to be stabilized by excavating material on the left bank.

The following observation have been made

- An overflow weir is to be constructed to pass the 1000-year flood. The river diversion during construction is to be managed through a deep cut channel on the left bank. Later on the same deep channel is to be used for sediment flushing by installing gates.
- For power intake, there is sound rock formation on the left bank just upstream of weir site. The access to the area can be made through adit and headrace tunnel. Steep slopes and weak geology have been observed for the headrace, penstock and powerhouse area.
- Headrace tunnel can be constructed at lower elevation of highways tunnel in same geological formation upto surge tank. The access to surge tank and headrace tunnel is available through old KKH.
- From surge tank to powerhouse area, embedded penstock can be laid down over mild slope terraces. The anchor block can be placed over rock/boulders.
- At the proposed site, surface powerhouse can be constructed. Surface powerhouse, tailrace channel and bifurcated penstock can be placed at required elevation by excavating the alluvium.

The Project Layout on the left bank is presented in Figure 7-1. Topographic conditions to propose Project Layout on the left bank are found favorable and considered suitable to propose a Project Layout.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

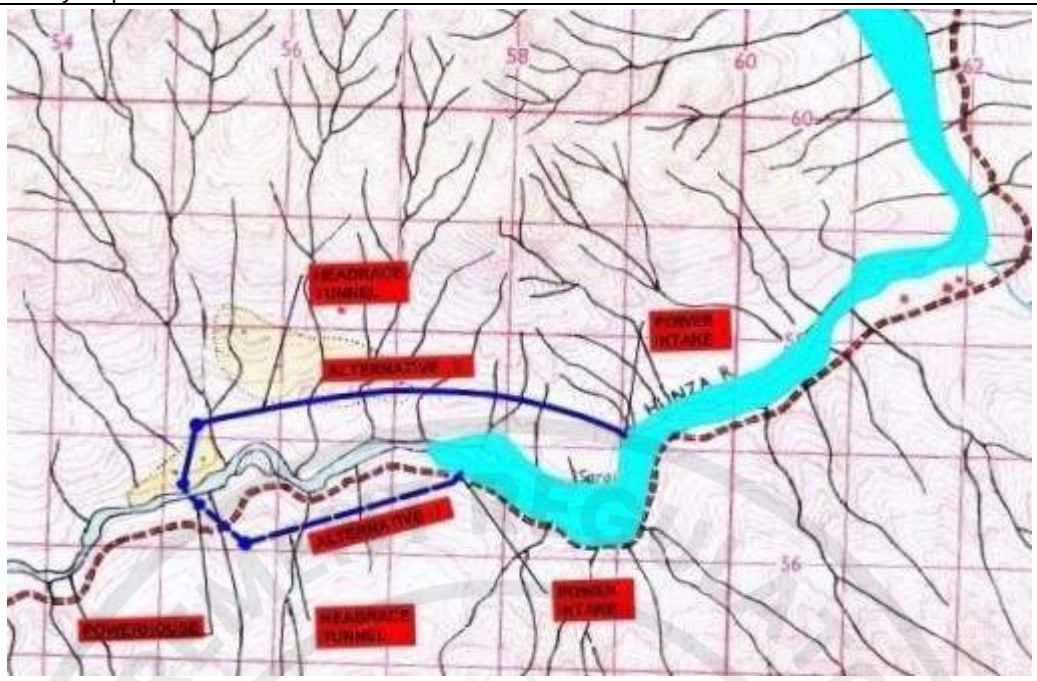

Figure 7-1 Alternative Project Layout on the Left and Right Bank

7.2.2 Alternative-II: Project Layout on the Right Bank

A Project Layout on the right bank have been studied with intake 1.6 km upstream and powerhouse 2.0 km downstream of weir site. A low pressure tunnel about 3.8 km length is to be constructed to utilize the available head at ALHPP.

The Project Layout on the right bank has geologically disturbed area and Attabad slide originated from the right bank and slided material fallen on the left bank. On the right bank of the River, there is excessive loose material present and it is considered susceptible to rock fall and minor slides due to its being fragmented. The accessibility to the right side is difficult and construction and operation of scheme on the right bank is technically unfeasible.

The right bank of the river is where the slide basically was initiated from, therefore, there is excessive loose material present and the mountain side is quite fragmented. Clearing the overburden to reach the rock face will not only require a lot of excavation, but also the site will remain susceptible to rock fall and minor slides due to its being fragmented. Operability of Project components on this bank will remain a challenge.

Considering the Project construction, operation and maintenance, environmental issues, stability of structures, the left bank layout has been preferred over that of the right bank and is selected for further studies.

7.3 FIELD INVESTIGATIONS FOR PROJECT LAYOUT

For Feasibility Study, field investigations like topographic survey, geological mapping, borehole drilling, test pits, environmental survey, flows and sediment observations have been carried out. For the identified dam / weir and the powerhouse site on the left bank of Hunza River near Attabad, topographic survey has been carried out, which is duly connected with Survey of Pakistan (SOP) Grid. The long term flow data of Hunza at Danyor Station has been used to estimate the daily flows and flow duration curves at the weir site. All the field data helped to finalize the structure locations and sizes for a technically feasible and economical layout.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Considering topographic and geological conditions at the weir and upstream valley, an overflow concrete weir at El. 2414 m a s l has been proposed with normal operating pond level as 2414 m a s l. The tailrace outlet of ALHPP has been planned at El. 2300 m a s l. Further 2 options have been studied on the left bank of Hunza River. i.e.

a. Alternative -I A Headrace Tunnel Option

b. Alternative -I B Headrace with Embedded Pressure Pipe T

7.3.1 Alternative-I A Headrace Tunnel Option

ALHPP has been envisaged with a 14 m high weir on Hunza River identified, 4 km downstream of Attabad Lake confluence with Hunza River and the powerhouse near Batakundi Village. The Project Layout includes power intake, sandtrap, headrace tunnel, surge shaft, in addition to ungated weir spillway and surface powerhouse on the right bank.

For the water ways from intake to surge shaft, two options have been considered; either headrace tunnel or pressure pipe. These two options have been studied with respect to powerhouse and preliminary cost estimates.

The salient features of Alternative Project Layout on the right bank are as under;

Salient Features Headrace Tunnel Option

The Salient Features of ALHPP layout for Alternative-IA are listed below.

a.	Weir/Dam Height	2.0 m
b.	Normal Reservoir Level	2414.0 m a s l
c.	Minimum Operating Level	2412.0 m a s l
d.	Live Storage	3.0 Million m^3
e.	Mean Annual Flow	209.0 m^3/s
f.	Design Discharge	60.0 m^3/s
g.	Turbine Level	2300.0 m a s l
h.	Maximum Net-Gross Head	108.1 m
i.	Minimum Net-Gross Head	105.6 m
j.	Headrace Tunnel Length	2300 m
k.	Penstock Length	550 m
l.	Type of Turbine	Francis
m.	Installed Capacity	54.0 MW
n.	Annual Energy Generated	374.0 GWh
o.	Plant Factor	79.0 %

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

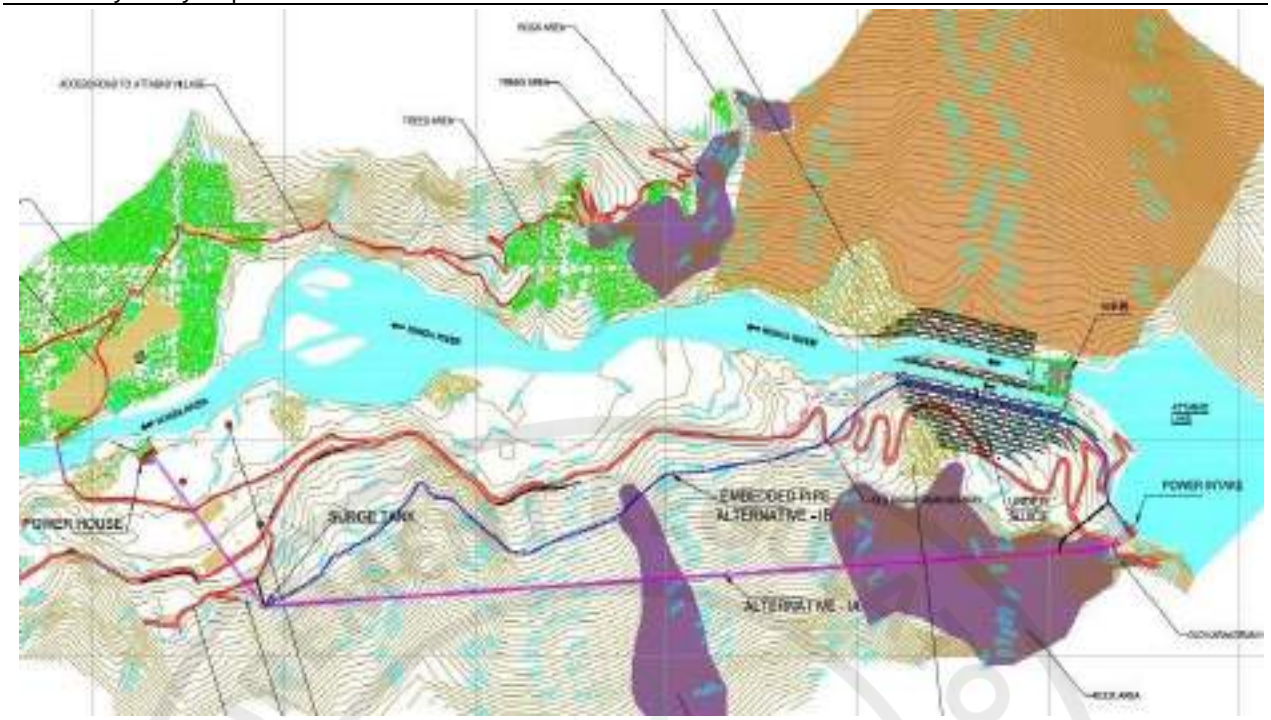

Figure 7-2 Project Layout on the Left bank with Tunnel and Penstock Options

7.3.2 Alternative-I B Headrace with Embedded Pressure Pipe.

The salient features of ALHPP layout for Alternative-IB are same except the following:

a.	Maximum Net-Head	102.1 m
b.	Minimum Net-Head	99.6 m
c.	Headrace pipe length	2.8 km
d.	Penstock Length	550 m
e.	Installed Capacity	51.7 MW
f.	Annual Energy Generated	357.8 GWh
g.	Plant Factor	79.0 %

7.4 EMBEDDED PENSTOCK VERSUS TUNNEL

Both the embedded penstock and tunnel options are considered for the conveyance of lake water for power generation along the left bank of the Attabad Lake. On the basis of field observations, on topographic survey, geological & geotechnical investigations, the embedded penstock route passes through overburden and its construction/installation will be quite hazardous as observed during geotechnical investigation. The cost comparison of tunnel and embedded penstock has also been carried out to check the suitability of conveyance of lake water. Cost comparison also shows that power tunnel option is more appropriate in view of least cost with less operation and maintenance issues that may encounter in case of embedded penstock alternative. Necessary geological studies, mapping and geotechnical studies including topographic surveys of cross drains along tunnel route and embedded penstock have also been carried out.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

7.4.1 Geology along the Embedded Penstock Route

The scree, moraines, debris flow, creeps and landslides are common along the whole ridge from intake area to powerhouse. These deposits are the results of broken rock fragments at the toe of hill slopes, mountain cliffs, and valley shoulders that has accumulated through periodic rock fall from adjacent cliff faces. These rock spreads have been marked on the geological map of the Project Area.

7.4.2 Geology along the Tunnel Route

Gneisses of Baltit Group are well exposed along the proposed power tunnel. These rocks are mostly over run by very loose unconsolidated material. This overburden material is composed of boulders, cobbles, pebbles, gravels and with fine grained sand and clays. To ascertain the dimensions of the spread of overburden, electrical resistivity survey along the power tunnel has been conducted.

7.5 POWERHOUSE LOCATION

Powerhouse location is affected by factors primarily associated with availability of head, favorable geology, availability of land and accessibility besides impact of powerhouse construction on habitants in the area (locality). Issues relating to protection against land sliding and flooding have also been taken into account. Keeping the above in view, only one location has been considered for powerhouse for both the alternates.

A surface power house is being considered on the left bank of Hunza River about 300 m upstream of Sarat Bridge. The terrace is large enough space for powerhouse, switchyard, offices and/or staff residences in the close vicinity of the powerhouse. The river bed level at the site is 2306 m.a.s.l.

7.5.1 Geology of Powerhouse

The proposed powerhouse is located on alluvium deposits. The slope is gentle along penstock area which is covered by overburden material. The rocks of Baltit Group are exposed along the penstock. Quaternary alluvium has been recorded along slopes and in the river banks and along the main tributaries. Scree and unconsolidated colluvial debris have been recorded along slopes which are commonly loose and un-cemented in nature.

For confirmation of thickness and properties of overburden material; four boreholes drilled at powerhouse, tailrace, penstock and surge tank locations have been drilled the detail of locations is marked on topographic survey map.

7.6 COST ESTIMATES

For the identified Project Layouts, based on preliminary dimensions of structures, cost estimates have been prepared for Alternative-I A and – I B. The summary of cost of various project components and E&M equipment are presented in Table 7-1

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 7-1 Estimated Project Base Cost

Sr. No.	Description	Total (Million Rs.)	
		Alter-IA	Alter-IB
A	**Preliminary Works and Environmental Cost**	1,161.40	1,161.40
B	**Civil Works**		
B-1	Main Weir	2,008.821	2,008.821
B-2	Sediment Flushing Channel	2,326.679	2,326.679
B-3	Power Intake	429.289	429.289
B-4	Low Pressure Headrace Tunnel	1,820.182	0.000
B-5	Surge Shaft	132.728	132.728
B-7	Penstocks	713.256	3242.063
B-8	Powerhouse	624.474	624.474
B-9	Tailrace Channel	84.318	84.318
B-10	Check Dams at Shimshal Nullah	392.500	392.500
	Sub Total B	8,532.247	9,240.872
	Total for Civil Works (A+B)	**9,693.642**	**10,402.267**
C	**HSS, Mechanical & Electrical Works**		
C-1	Hydraulic Steel Structures (HSS)	139.730	139.730
C-2	Power House Mechanical Works	1,690.890	1,690.890
C-3	Power House Electrical Works	2,249.339	2,249.339
C-4	Switchyard works	428.453	428.453
C-5	Transmission Line (Single Circuit Attabad to Sost & Double Circuit Attabad to Aliabad)	1,500.135	1,500.135
	Sub Total for C-1 to C-5	6,008.547	6,008.547
C-6	Transportation Charges of E&M Equipment @ 7%	420.598	420.598
C-7	Erection & Commissioning Charges @ 8%	480.684	480.684
C-8	Government Taxes on E&M Equipment @ 16%	961.368	961.368
	Sub Total C for E & M	**7,871.197**	**7,871.197**
D	**Project Construction CostSub Total A, B & C**	**17,564.84**	**18,273.46**
E	Indirect Cost	2464.076	2563.48
F	**PROJECT BASE COST**	**20,028.916**	**20,836.94**

For the two alternatives, power and energy have been computed for a design discharge of 60.0 m^3/s. The comparison of cost/kWh is presented in Table 7-2.

Table 7-2 Comparison of Alternatives

Project Components	**Alternative-I A** Headrace Tunnel	**Alternative-I B** Pressure Pipe
Project Base Cost (US$)	20,028.916	20,836.94
Power (MW)	54	51.7
Energy (GWh/year)	373.69	358
Energy Cost/ (USc/kWh)	3.61	3.93

The comparison of two alternative layouts indicate that Alternative IA has lower cost and will produce more energy/year, therefore cost/kWh is less as compared with that of Alternative-II B. Project layout with headrace channel is recommended for further studies.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

7.7 SELECTED PROJECT LAYOUT

With favorable topographic and geological conditions for the Project Area. The Project Layout (Alternative-I A) with low pressure tunnel on the left bank is preferred over other available options. The availability of recorded flows of Hunza River at Attabad provide the basis to have design discharge of 60.0 m^3/s and installed capacity of 54 MW for ALHPP.

The Project Layout (Alternative-I A) on the left bank with identified weir site, 2.3 km long headrace tunnel, 550 m embedded penstock and surface powerhouse near Hunza River is considered the only technically sound and economical layout. Hence, it is recommended for further studies.

PUBLIC PROCUREMENT REGULATORY AUTHORITY (PPRA) EPADS

8 POWER POTENTIAL

8.1 GENERAL

The demand for electricity varies seasonally. In lower areas of the country demand reaches to its maximum in summer season and remains lower in winter. But in northern area of the country specially in Gilgit-Baltistan (GB) demand for power and energy is maximum in winter season and remains within lower ranges in summer. Electricity demands also vary during the same day, people use more power in the morning and in the evening. Therefore, many powerhouses are managed to tackle such peak times. For this purpose, temporary storage is done in the lake/pond/forebay and releases during peak hours. Such projects have small storage as compared to large dam's storage.

As the lake had already been developed so reservoir capacity has not been enhanced than present to avoid inundation of upstream areas due to increase of water levels, however, flushing will be carried out to retain the present capacity of the lake.

8.2 RESERVOIR OPERATION SYSTEM

ALHPP is located on Hunza River and there is no other considerable power project on main Hunza River which could influence the operation of ALHPP, further, there is no irrigation system which could be supplemented from Hunza River. Therefore, the Project is only for power generation.

The amount of hydropower generated depends upon the volume of water and the effective head. Reservoir operation and corresponding power potential has been studied for 50 years (1966 – 2015) in order to assess the true power potential of the Project.

It is proposed to operate the reservoir to provide diurnal storage in the low flow periods to enable peaking energy to be generated in preference to base energy when there is insufficient flow to generate continuously. The daily storage required for 4 hours peaking is 0.864 Mm3and storage required for 24 hours at full capacity is 5.18 Mm3, which is equivalent to all the volume available in the upper 1.25 m of the reservoir.

The following definitions of Peak Energy, Primary Energy and Secondary Energy were used:

- On-Peak Energy is defined as the energy that the plant can produce during four hours per day (peak demand hours) with at least 95% reliability. The On-Peak Energy is assumed to be the best remunerated.

- Off-Peak Energy is defined as the energy produced by the plant off the assumed 4 hours of daily peak demand.

- Firm Energy is defined as the energy that the plant can generate with 95% reliability, which is, deficits shall not occur for more than 5% of the time.

- Secondary Energy is the energy that the plant can produce in excess of the Firm Energy. Secondary Energy is produced only when the reservoir is full, and is limited by the capacity of the plant.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

From power generation point of view, the primary target of the operation is to assure the highest possible peak generation: a general criterion considered was to assure at least 4 hours per day of operation at full capacity.

A second target of the operation is to maximize the firm energy production, which is the energy which can be guaranteed in each month with a sufficiently high level of reliability: in principle, a 95% reliability criterion for the firm energy has been considered.

8.3 ATTABAD RESERVOIR

As discussed earlier, reservoir capacity of the lake has been reduced from 250 Mm3 to 125 Mm3 which indicates that half lake capacity has been filled with sediments during the last 10 years. Therefore, in order to retain the lake capacity and utilize this hydro potential for the generation of electricity regular flushing would be carried out along with power generation. Under sluice Channels proposed for this purpose.

To study the power and energy potential of the Project, hydrographic survey is used to assess the lake's capacity with respect to the elevation. The present reservoir extends more than 12.5km, to actualize the present storage with respect to area and elevation in terms of Storage-Area-Elevation curve is given below

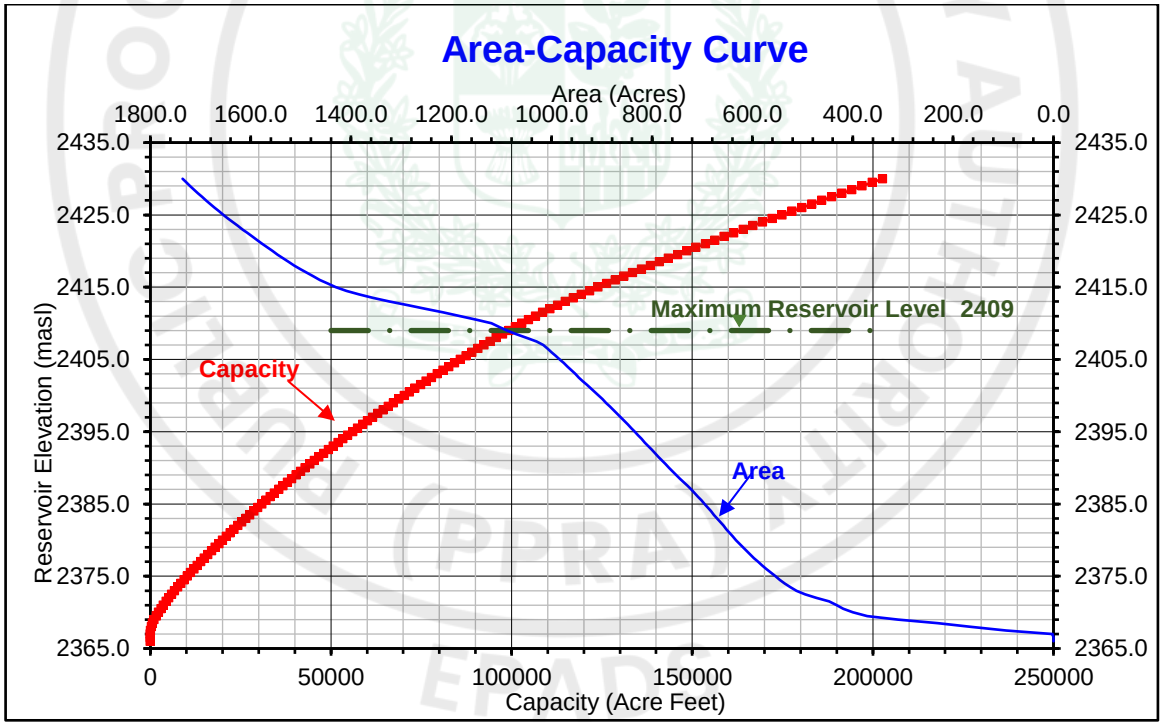

Figure 8-1 Area Capacity Curve

8.4 WATER AVAILABILITY AT RESERVOIR

Mean annual flows are calculated for the period 1966-2015. Average value for mean annual flow has been calculated as 208.36 m^3/s. Flows are generally maximum in July and August almost touching 700 m^3/s. Whereas, flows are low from December to April each year when snow falls in the catchment. The graph shows that design discharge of 60 m^3/s is available for about half year (almost 6 months). Graph also shows that flows are exceeding the design discharge from June to mid-December which shows the potential of hydropower generation

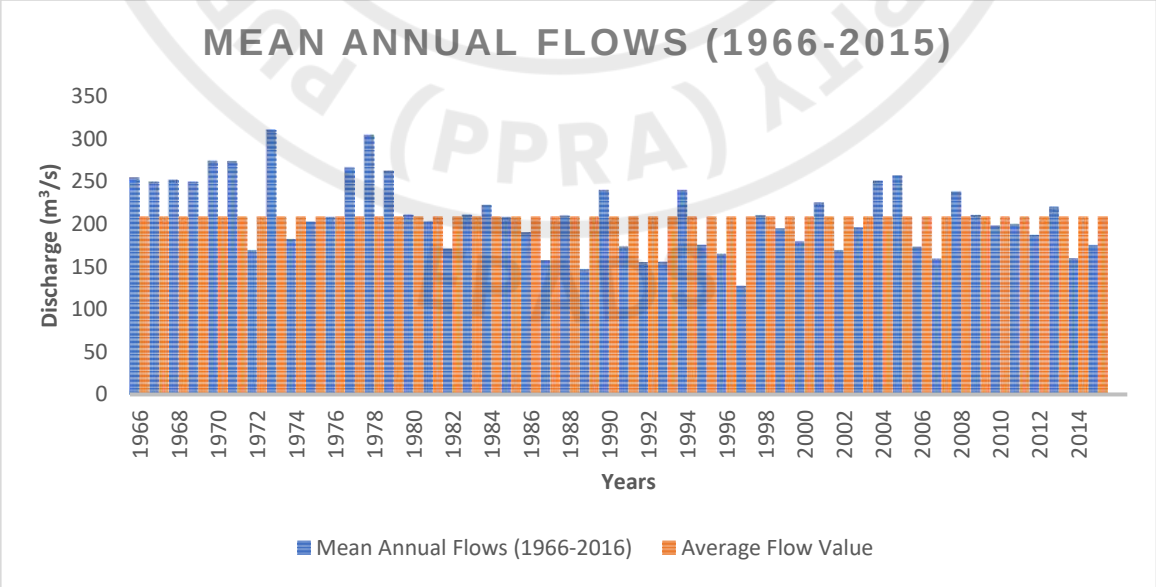

Figure 8-2 Mean Annual Flows

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

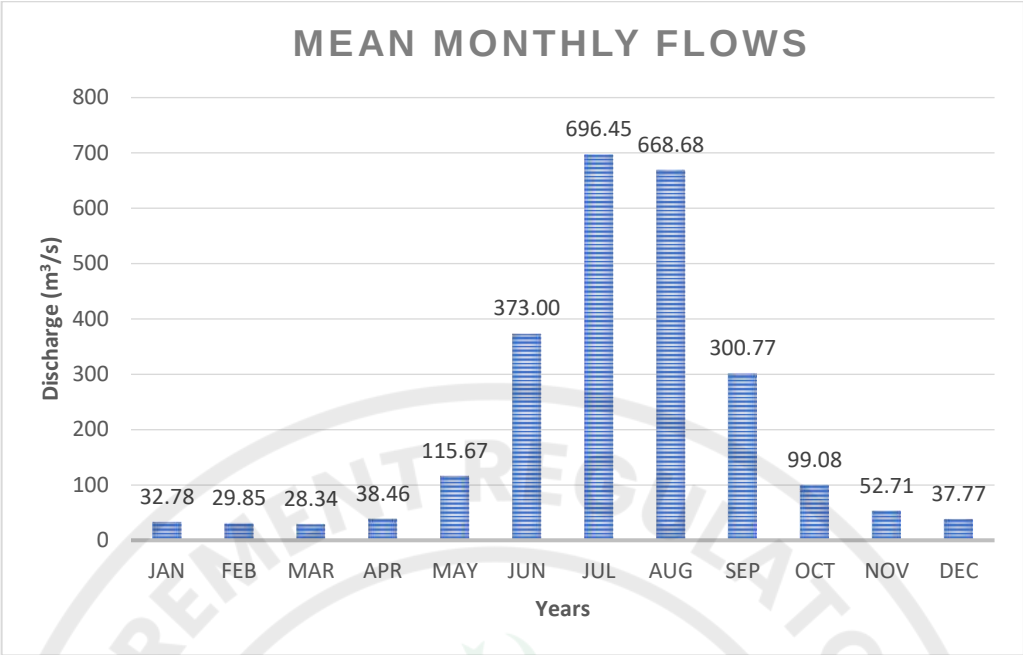

Figure 8-3 Mean Monthly Flows

Maximum, Mean and Minimum daily flows for the period 1966-2015 are also plotted in the Figure below to depict the flow pattern at Attabad Lake site.

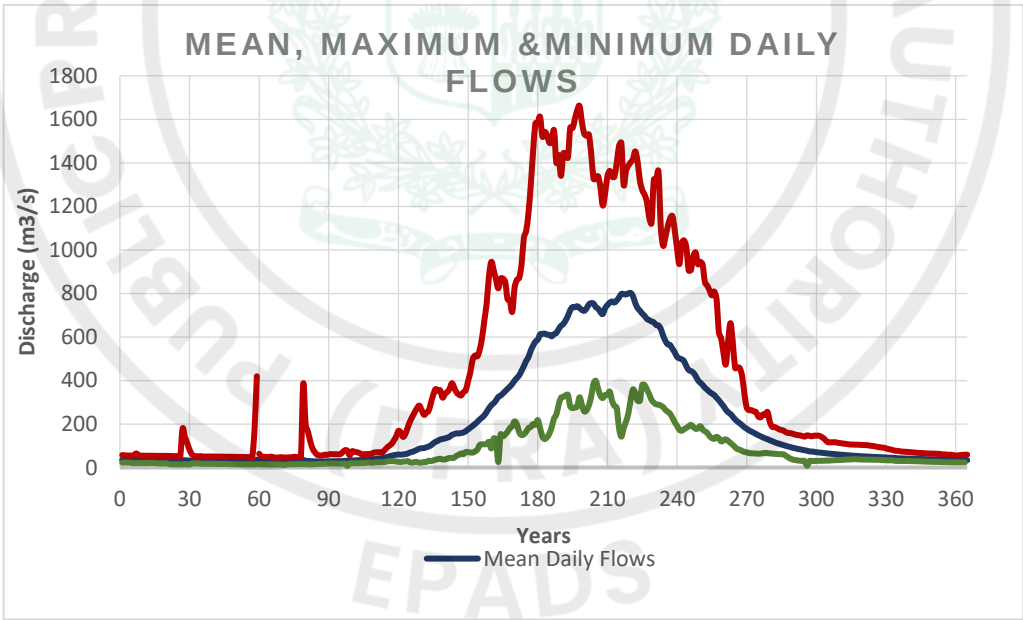

Figure 8-4 Mean, Maximum & Minimum Daily Flows

8.4.1 Flow Duration Curve (FDC)

Flow Duration Curve (FDC) for Attabad Lake HPPLHPP is plotted on the basis of almost 51 years (1966-2016). From FDC it is evident that design discharge of 60 m^3/s is available for almost 50% of the time. Therefore, design discharge of 60 m^3/s is justified for the generation of 54 MW power.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

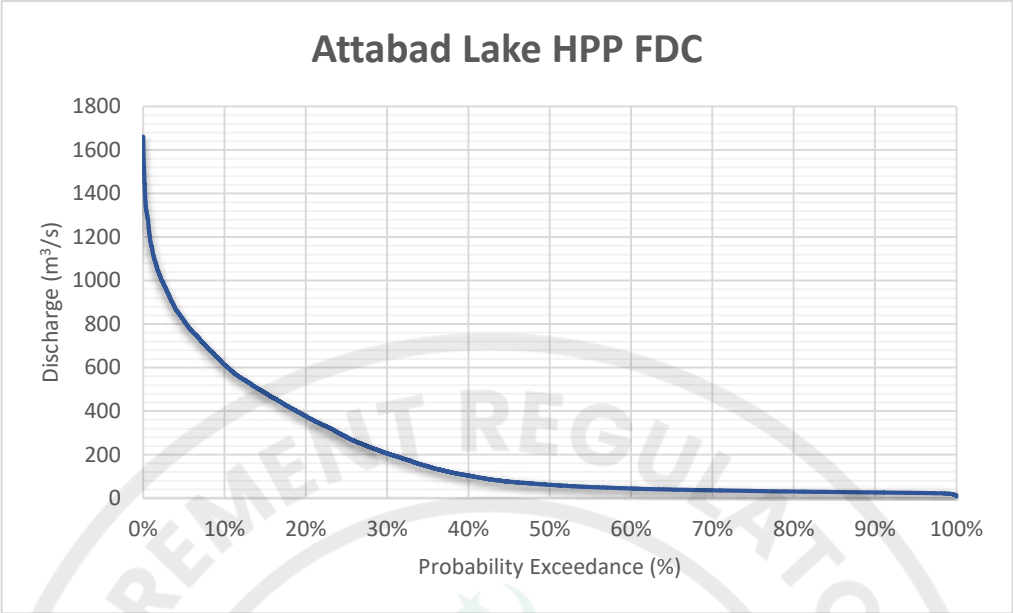

Figure 8-5 Attabad Lake Flow Duration Curve (FDC)

Table 8-2 Flow Duration Curve Results

Probability Exceedance (%)	Flow (m^3/s)	Probability Exceedance (%)	Flow (m^3/s)
10	613.4	60	44.3
20	376.6	70	36
30	205	80	30.3
40	103.3	90	26.2
50	61.3	99	20.5

8.5 WATER LEVELS

The available head for power generation has been determined from normal operative level and the water level where tailrace channel joins Hunza River.

8.5.1 Upstream Water Levels

Upstream water levels have been determined keeping in view the operation of the Attabad Lake. For power and energy estimates, the normal operative level varies from 2,412 m.a.s.l to 2,414 m.a.s.l.

8.5.2 Downstream Water Levels

The tail-water rating curve for downstream of the powerhouse at Hunza River is obtained using the water levels, historic discharges and cross section of Hunza River. Calculations are tabulated at Table 8-3 and the tailwater rating curve is plotted at Figure 8-6. The downstream tail water rating has been adopted for stage estimation downstream of power house. The head losses expected to occur in the power scheme have been calculated to determine the net head available for power generation.

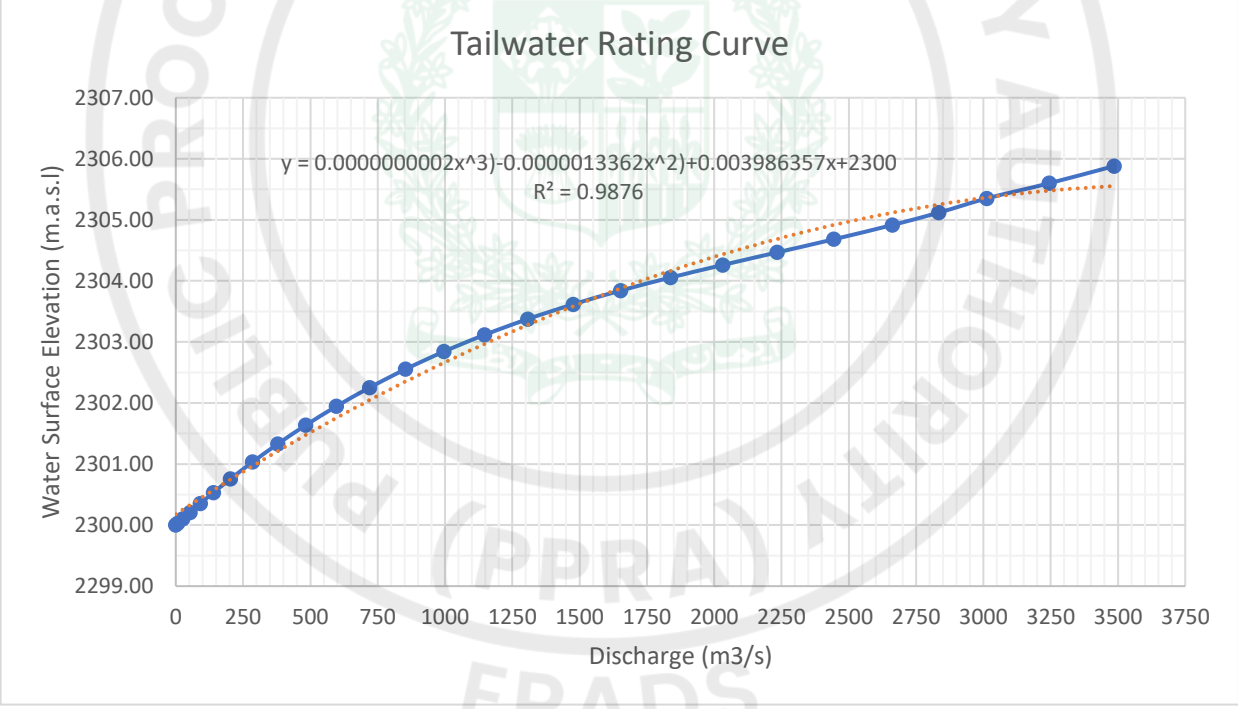

Figure 8-6 Tailwater Rating Curve

8.6 POWER AND ENERGY STUDIES

8.6.1 Power and Energy Potential

Power and energy potential at the site have been estimated on average 10-daily basis using time series data from 1966 to 2015. Available head across the hydropower facility has been computed keeping in view the minimum and maximum operation water levels i.e. 2,012 to 2,014 m.a.s.l. Tailwater rating curve has been used for estimating the tailwater levels on the downstream side for determining the head available for power generation.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The power estimates have been computed by using the following formula:

$$P = \frac{\gamma \times n \times g \times H \times Q}{1000}$$

where,

P	=	Power output, 54 MW
ρ	=	Density of water, 1,000 kg /m3
g	=	Gravity acceleration, 9.81 m/s2
η	=	Overall efficiency of the hydroelectric plant 88.32%
Q	=	Design discharge, 60m3/s
H	=	Net Head varies between 105 m to 107.5 m depending head wa ter levels

Table 8-4 Efficiency Coefficients of Various Power Plant Components

Component	**Efficiency**
Turbine & Speed Increaser	91.5%
Generator	97.5%
Transformer	99%
Overall	88.32%

The average daily energy has been calculated as follows:

$$E = \frac{P \times h \times d}{1000}$$

where,

E	=	Energy output (GWh)
P	=	Power output (MW)
h	=	Hours in a day
d	=	Number of days in each time step

8.6.2 Optimization of Power and Energy

In previous studies, 32.5 MW capacity plant had been proposed for this project, however, keeping in view the potential of the lake and availability of head, the power and energy optimization have been carried out to size the plant. Upstream water levels and tail water rating along with the average flow data for the period 1966 to 2015 have been used for calculating the power, energy and plant factor. Comparison of power and energy potential of this study with the previous study has been tabulated below:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 8-5 Summary of Power & Energy Potential

Power and Energy Parameters	As in Previous Studies Conducted through Consultants	As in this Study Conducted by WAPDA
Design Discharge (m^3/s)	40	60
Gross Head (m)	106	112
Power Capacity (MW)	32.5	54
Mean Annual Energy (GWh)	256.66	373.69
Plant Factor (%)	92.70	79

8.6.3 Plant Factor

The Plant Factor is the unit-less ratio of an actual electrical energy output over a given period of time to the maximum possible electrical energy output over that period.

The plant factor which provides the basis for the installed capacity of the project is calculated as follows:

pf = (E/(P*8.760))*100

Where as

pf = Plant factor (%)

E = Mean annual energy (GWh/annum)

P = Installed Capacity (MW)

Hydraulic Losses

The hydraulic losses have been calculated using Darcy' Weisbach equation for pipes and hydraulic losses for different discharges keeping all other parameters same given in Table 8-6.

$$h_L = \frac{fLV^2}{2gD}$$

Where

h_L = Friction head losses in meters (m)

f = Moody's Friction Factor

D = Diameter of conduit in meters (m)

G = Gravitational acceleration (m^2/s)

L = Length of conduit in meters (m)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The summary of head losses is given in the following table

Table 8-6 Total Hydraulic Loss at Different Discharges

Discharge (m^3/sec)	Total Loss (m)	Discharge (m^3/sec)	Total Loss (m)
10	0.22	**60**	**6.04**
20	0.71	80	10.69
40	2.71	100	16.67

Net Head

After establishing the gross head, it is important to allow for the losses arising from laying of conveyance system. The gross head minus the sum of all loses through conveyance of flow for entrance to exist equals the net head. The range of net head varies between 105 to 107.5 m.

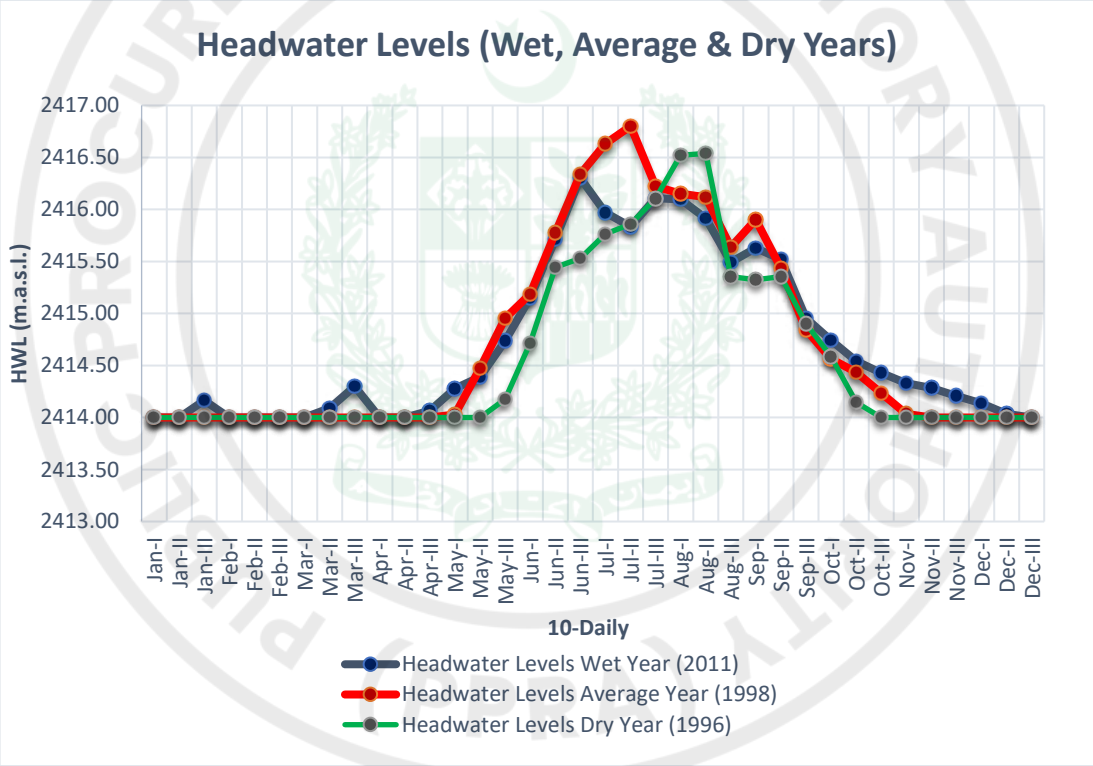

Figure 8-7 Headwater Level Variations (Wet, Average & Dry Years)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

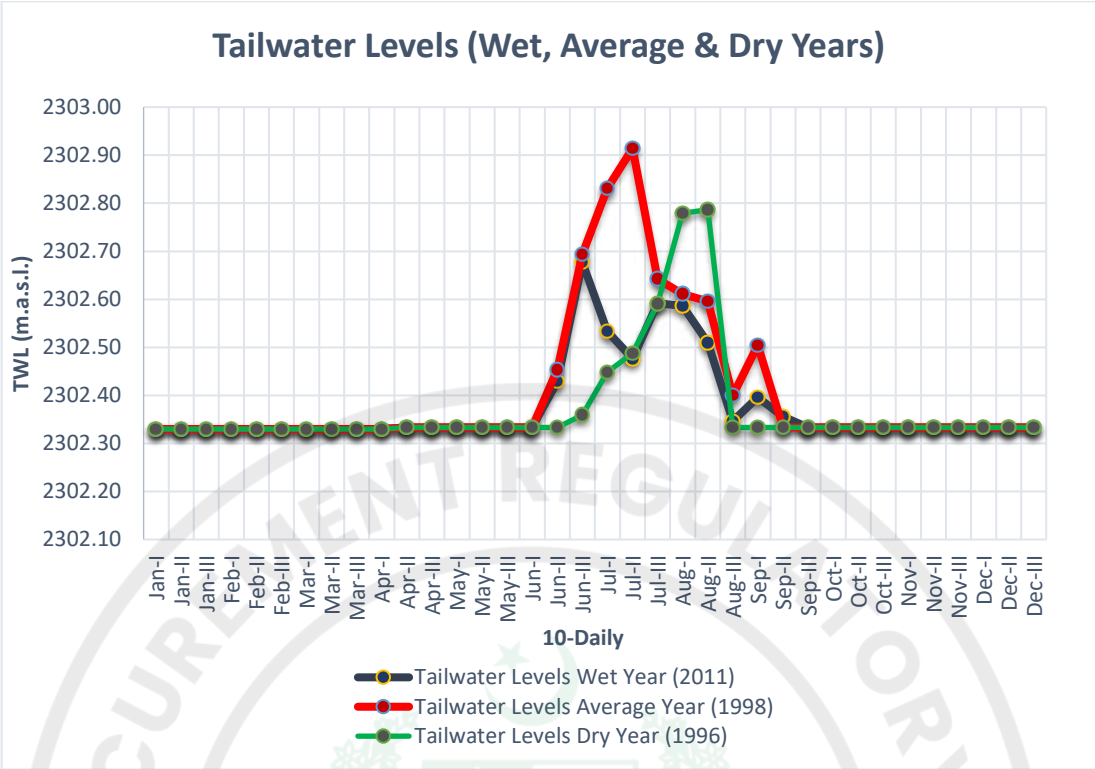

Figure 8-8 Tailwater Level Variations (Wet, Average & Dry Years)

Basic Assumptions in Calculations

The following basic assumptions have been made in estimating power and energy of the identified schemes.

- The residual water has been maintained in that 2 km reach i.e. weir to powerhouse site for ecological purposes and for calculations of power and energy.

- The variations in the efficiencies of generating units due to change of net heads have not been considered. For design discharges available to powerhouse, an efficiency of 91.5%, 97.5% and 99% have been used for the turbine, generator and transformers, respectively.

8.7 ESTIMATED POWER AND ENERGY

Keeping in view all the aspects, selected optimized design discharge is 60 m^3/s, the power and energy have been estimated on the basis of 10 day flows for all years from 1966 to 2015. For 10-Daily Power Curves, the optimum installed capacity would be 54.0 MW with environmental flow of 3 m^3/s having mean annual energy of 373.69 GWh. The plant factor will be taken as 79%.

The calculated annual energy, for years 1998 (average year), 2011 (wet year) and 1996 (dry year), is 375.75, 449.49 and 333.87 GWh respectively. The energy calculated based on 10 daily flows for 50 year ranges between 333.87 GWh to 449.49 GWh.A mean value of 373.69 GWh has been taken as mean annual energy. The 10 daily power and energy for average, wet and dryyears are presented in Table 8-7, 8 and 9 respectively, whereas power curves for these three scenarios are shown in Figure 8-9, Figure 8-10 and Figure 8-11 respectively.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

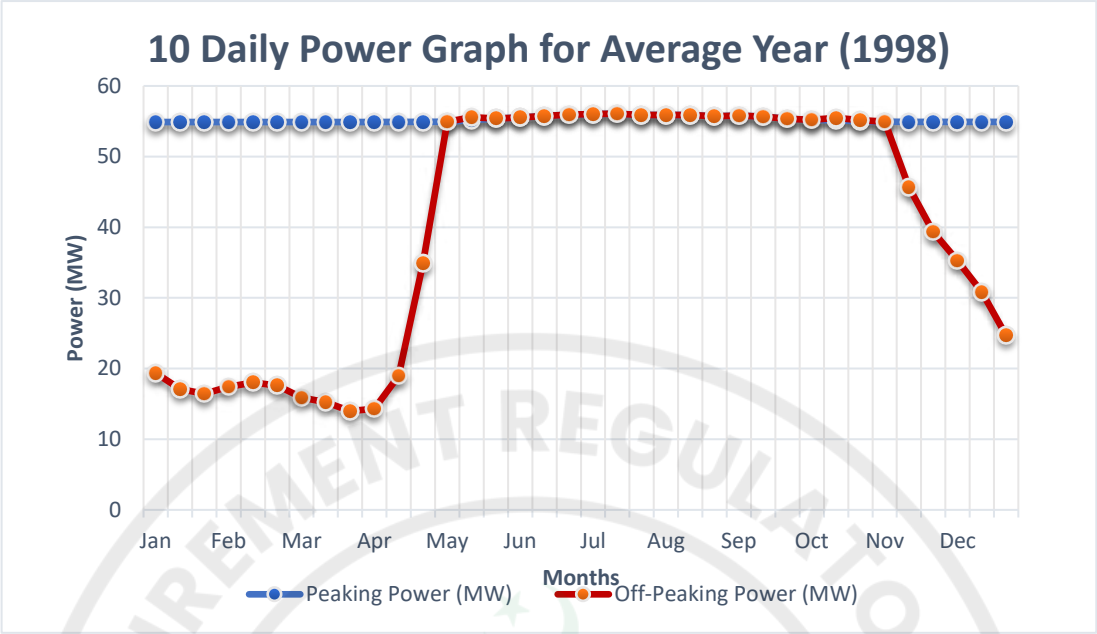

Figure 8-9 10-Daily Power Graph for Average Year (1998)

As in average year, the installed power of 54 MW would be available for 24 hours from May to October. Peaking power (4 hours) will be available throughout the year, however, off-peak power (20 hours) will vary from 14 MW to 54 MW and will remain full from May to October. When flow reduces due to winter in November, the power generation would also reduce, however, enough flows remain available to run one turbine unit during lowest flow period as indicated in Figure 8-9.

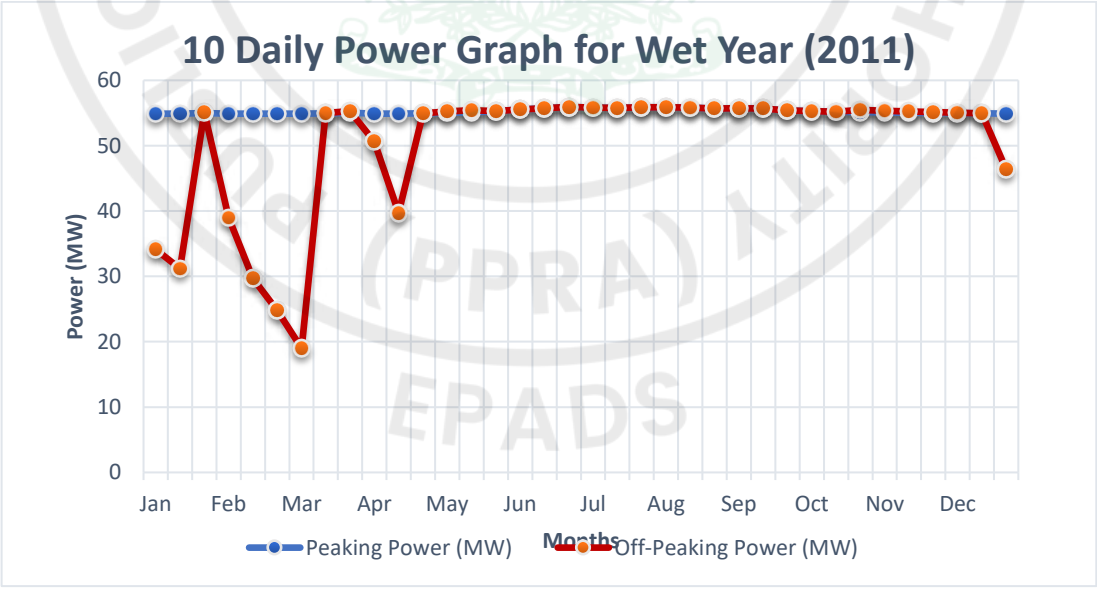

Figure 8-10 10-Daily Power Graph for Wet Year (2011)

In wet year, installed power of 54 MW would be available from May to mid-December. Power may reach to full capacity during high flows of wet year even in February and March. In low flow period, the minimum power is estimated to remain at 20 MW as indicated in Figure 8-10.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

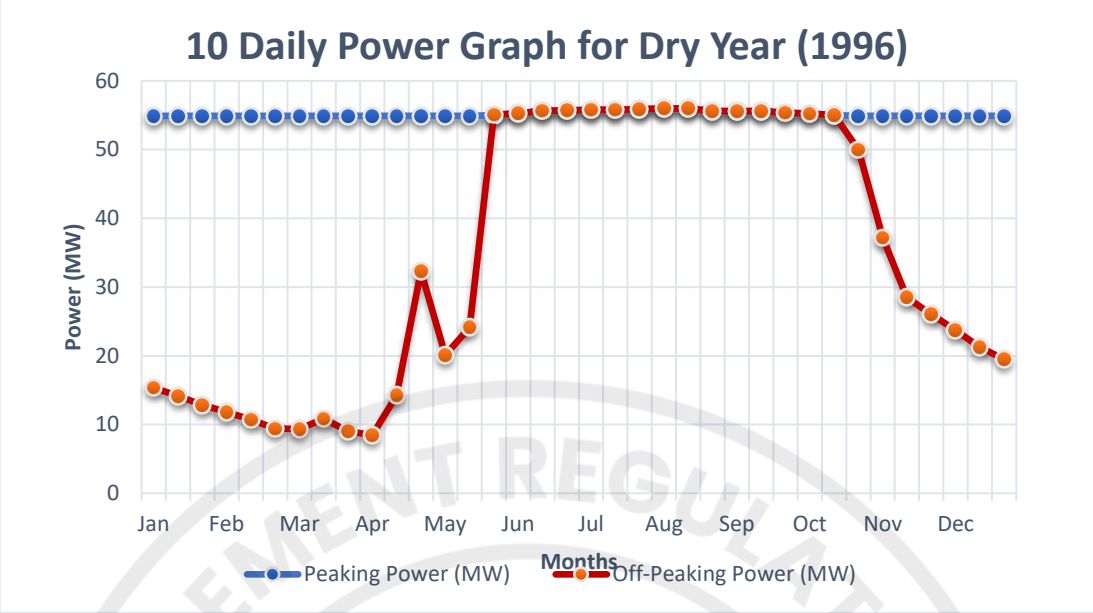

Figure 8-11 10-Daily Power Graph for Dry Year (1996)

In dry year, installed power of 54 MW will be available from June to mid-October and reduces as low as 9 MW when less flows are available. For dry year 1996, the power variation over the year is indicated in Figure 8-11.

The mean annual energy for the recorded period from 1966 to 2015 has been estimated and it is graphically presented in Figure 8-12. The graph indicates that the estimated annual energy over a period of 50 years doesn't vary much and remain quite consistent with little variation. It varies from 333.87 GWh to 449.49 GWh with mean value as 373.69 GWh. The plant factor for 54 MW power plant would be 79%. The low variation in mean annual energy and high plant factor indicate the reliability of hydropower from the lake.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

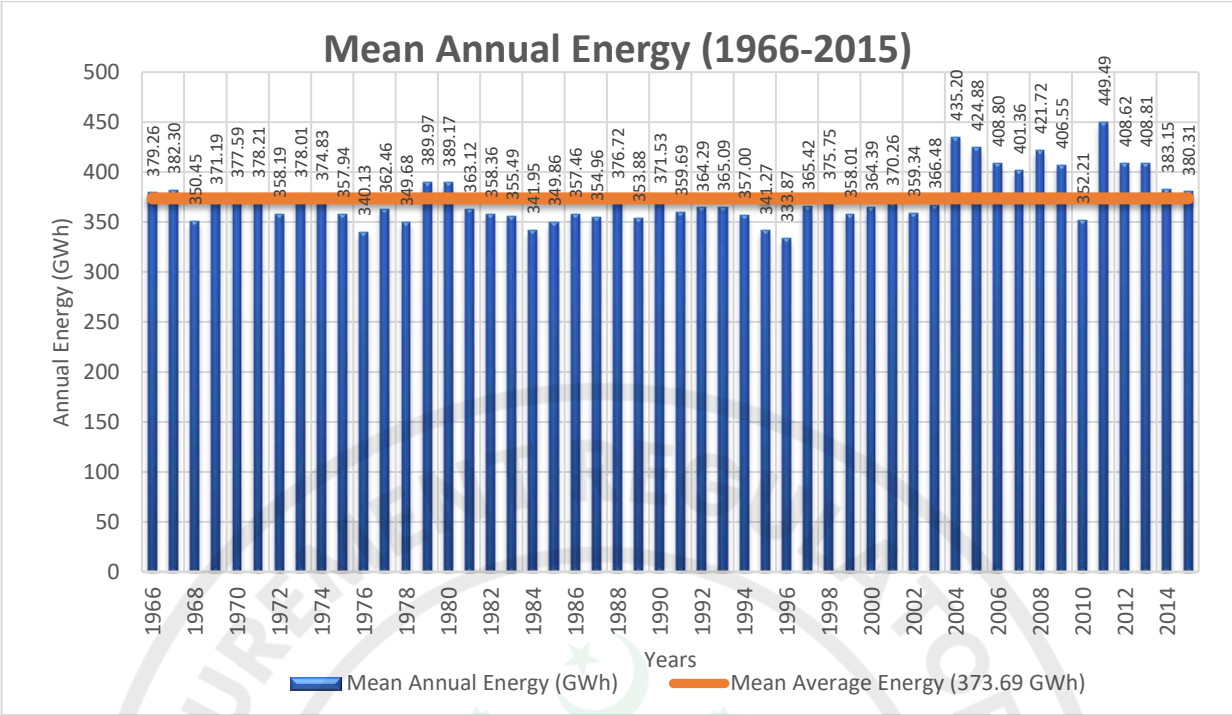

Figure 8-12 Mean Annual Energy Graph from 1966 to 2015

A comparison has also been plotted between monthly energy generations for Wet, Average and Dry years. Mean Annual Energy Curves indicate the trend of variations of monthly energies in GWh. The graph is shown at Figure 8-14.

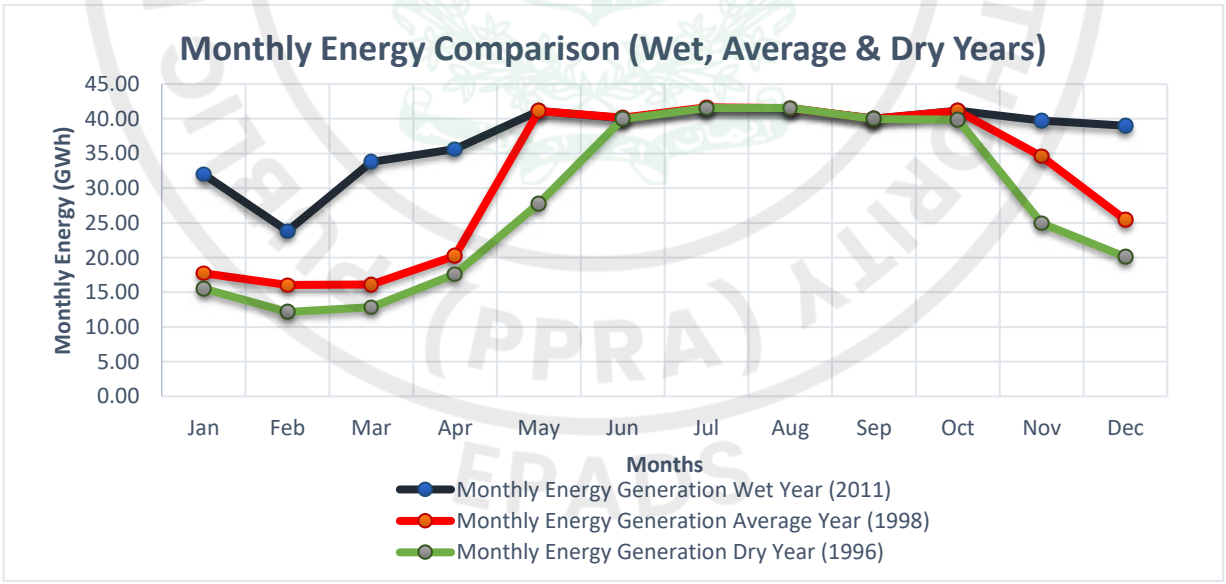

Figure 8-13 Monthly Energy Comparison (Wet, Average & Dry Years)

Power and energy calculations for Average, Wet and Dry years have been calculated and tabulated at Table 8-7, Table 8-8 & Table 8-9 respectively

9 DESIGN OF STRUCTURES

9.1 INTRODUCTION

Attabad Lake Hydropower Project (ALHPP) is a Runoff River peaking scheme on Hunza River in Hunza Region. The Project is planned to develop the reach of river 2.5 km downstream of Attabad Lake to generate 54 MW power by proposing the following Civil Engineering Structures:

Natural dam of 45 m height from river bed to act as diversion structure with low level outlet and an overflow ungated spillway.

Power Intake structure is proposed on the left bank of river to take the design discharge of 60.0 m^3/s.

- Low pressure headrace tunnel having diameter of 5.5 m with total length of 2320 m.
- Vertical surge shaft of 10 m diameter with height of 49 m.
- Concrete lined pressure shaft of 3.6 m diameter having a length of 80 m.
- Steel penstock having a length of 470 m length and diameter of 3.5 m.
- Surface powerhouse with three (03) Francis units with an installed capacity of 54 MW and open switchyard.
- Tailrace channel of 18 m length.

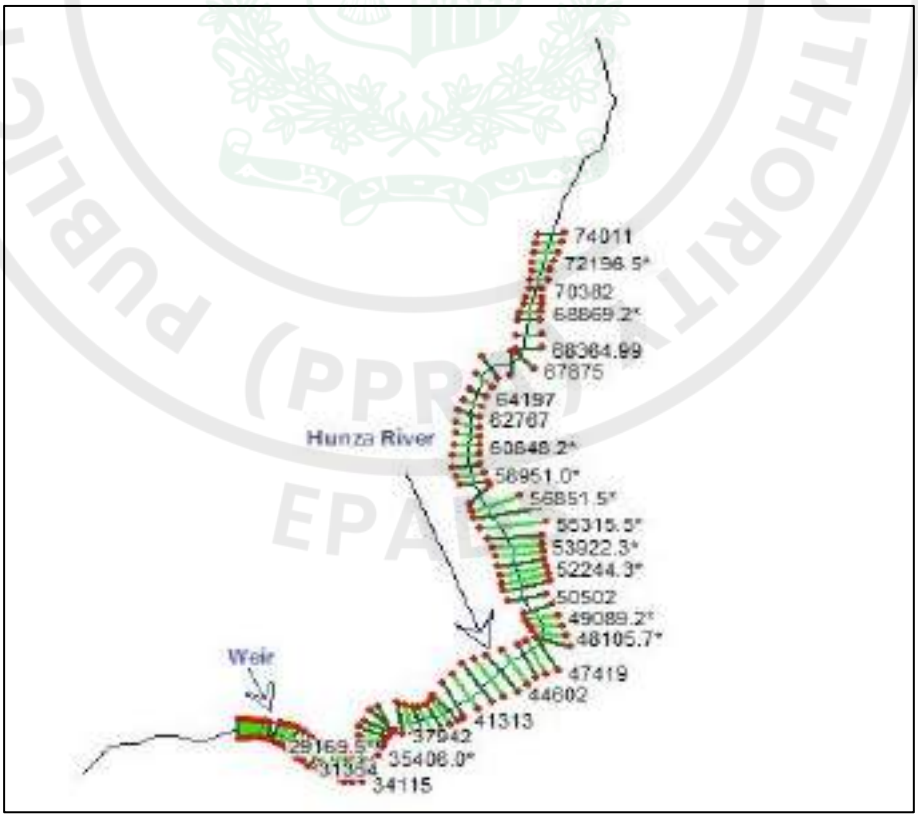
The overflow weir/ungated spillway on existing dam created due to landslide at right side of Hunza River has been proposed with its crest level at elevation 2414.0 m.a.s.l. The structure has been designed to safely pass 1:10,000-year return period flood and Operating Basis Earthquake (OBE) and Safety Evaluation Earthquake (SEE) without damage. The overflow weir/spillway is ungated structure for flood discharge. The discharge to downstream stilling basin of overflow weir/spillway for energy dissipation before being released into channelized section of Hunza River in slide area. The care has been taken to provide protective design of the structures. Detail Drawings of over flow weir/ spillway are shown in AFS-WR-409 to AFS-411 Vol. 2 Drawings.

Three low level sediment flushing outlets serving the dual purpose of diversion during construction as well as sediment flushing have been provided on the left bank of overflow weir/ungated spillway. Considerable sediment inflow is expected into the reservoir during the glacier/snow melt runoff and also during rains. In order to maintain the power intakes free of sediment build up, it is located 2 m above the invert level of flushing outlets. The concrete spillway section and the three low level outlets will be used to flush the sediments from the reservoir.

Due to the high river bed gradient, it is expected that intensive sediment load would be entering in the reservoir. To prevent this occurring, provision has also been made to build a low “flow-through” rockfill boulder trap on Shimshal River upstream of the reservoir to trap any moving boulders or bed material.

Two boulder traps will be constructed on Shimshal River which is main sources of sediment load in Hunza River at Attabad. Each boulder trap will be 20 m high an estimated boulder/debris/sediment volume of 1.4 Million m^3. The diversion of Hunza River will be accomplished by the construction of upstream and downstream cofferdams with impervious cut off provided by intersecting columns of jet grouting.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026



Conventional ring cofferdams with sufficient space provision for construction activities and access will be used for construction of the diversion intakes and tunnels and the power intakes. The headrace commences at the twin intakes on the left bank connecting to the low pressure tunnel.

At the downstream end of the low pressure tunnel a surge shaft is provided to limit pressure rise in the waterway system and allow flexibility in power plant operation. From surge tank, first horizontal tunnel and the embedded penstock lead to three vertical shaft Francis Turbines arranged in on-ground powerhouse. Transformers are arranged in a GIS open switchyard. The switchyard is above ground located near the powerhouse. A 18m long tailrace releases generation flows back to the Hunza River about 2.5 km downstream of overflow weir. Feasibility Drawings are provided in Vol. 2 – Drawings of the Feasibility Report.

9.2 HYDRAULIC MODELLING OF RESERVOIR

The primary tools for simulating the flow phenomena in water resources structures are hydraulic/hydrodynamic models that describe the fluid motion and the dynamics of the flood wave by solving mathematical equations, which are based on the principles of the conservation of mass and momentum.

Hydraulic Model, the Hydrologic Engineering Center's River Analysis System (HEC-RAS 5.0.7) is used to assess the impact of design flood on the proposed weir, downstream as well as backwater effect at the upstream side of the lake. The software is developed by the US Army Corps of Engineers and it is widely used for performing 1D steady and unsteady flow, 2D unsteady flow river hydraulics calculations, sediment transport modeling, and water quality analysis.

Figure 9-1 Reservoir Area showing River Cross Sections and Location of Weir

9.2.1 Input Data

Hydraulic Model is prepared to analyze the impact of flood of 3,250 m^3/s, 10,000 year return period flood, at upstream side of the project with proposed weir. A 1D-Unsteady numerical modeling approach is used in the analysis to study the impact of proposed weir having crest elevation of 2,014 m.a.s.l.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

River cross section data has been taken from the hydrographic survey conducted for the project by ISRIP in Sep/Oct 2020. Forty Cross Sections in about 14 km reach has been used to prepare an input file for HEC-RAS. These surveyed cross sections are further used for interpolation of cross sections where required for true representation and model stability. A proposed 60 m long ungated ogee weir and about 400 m downstream reach covering stilling basin and stone apron have also been drawn. In most upstream part of the reach, Manning's 'n' value has been taken as 0.040, value changes just before the weir structure and at weir crest it has been taken as 0.013 and accordingly downstream, Coefficient of Discharge (Cd) is taken as 0.8. Further, boundary conditions are set as flood hydrograph for 3,250 m^3/s peak and normal depth at downstream.

9.2.2 Analysis and Conclusions

The model has been run keeping a lesser time step for computations and accordingly results are computed. It can be viewed from the results that maximum Water Surface Elevation (WSE) at overflow Weir is 2,421.43 m.a.s.l. and about 14 km upstream it is 2,422.61 m.a.s.l. against design flood. This shows the impact of flood wave at upstream of the lake with 60 m long ungated weir having crest at 2,414 m.a.s.l. Flood mapping is drawn using RAS Mapper tool in HEC-RAS which shows the extent of maximum water surface elevation against the design flood. Rating Curve is also drawn at the weir. The model is calibrated using the flows measurements at Ganish Bridge and water surface level measurements at the lake during hydrographic survey.

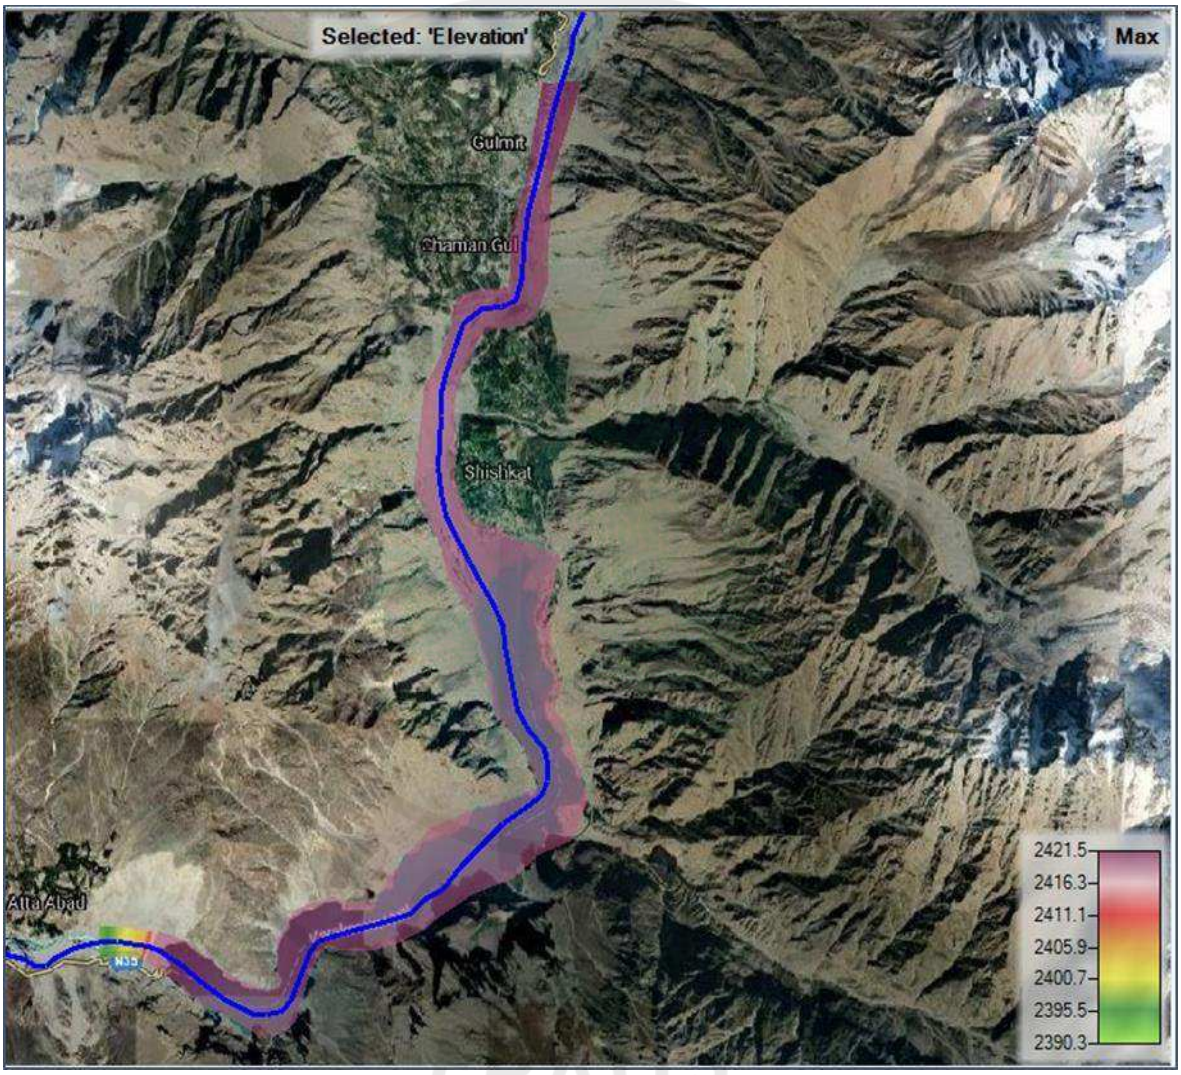

Figure 9-4 Maximum Water Surface Elevation (WSE) against Design Flood

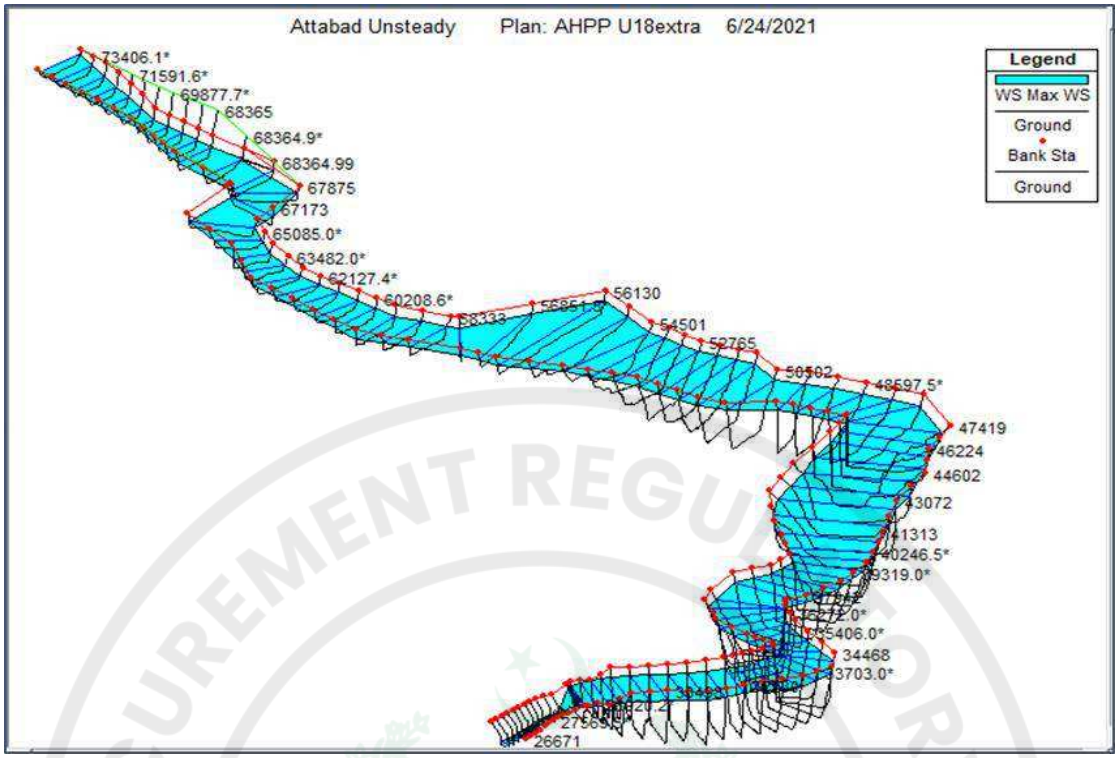

Figure 9-5 3D Perspective Plot against Max WSE

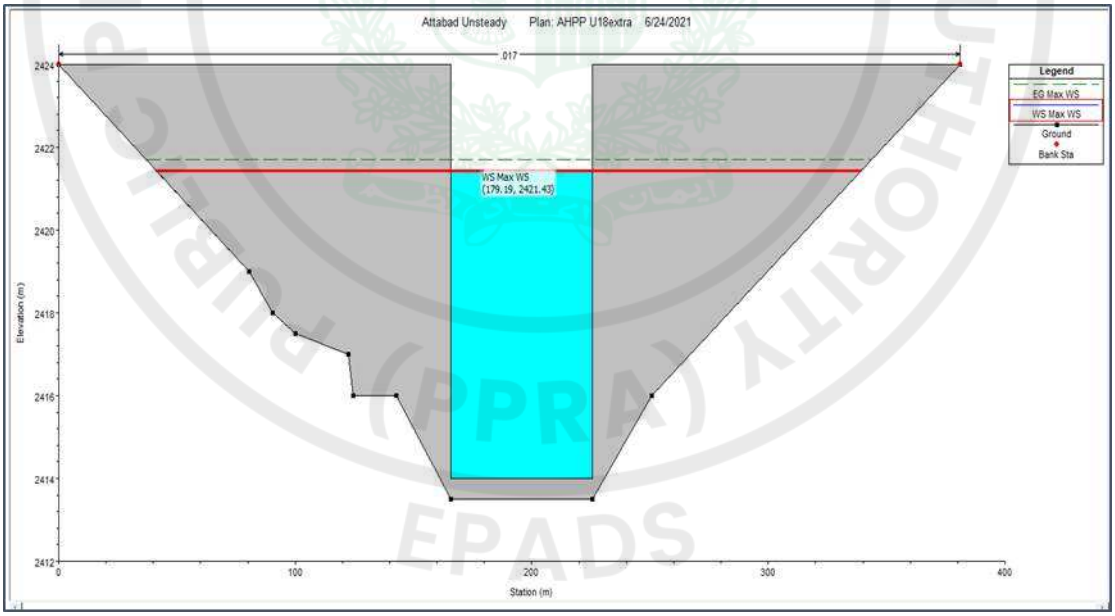

Figure 9-6 Weir Section with Maximum Water Surface Elevation

Detailed output table is tabulated below showing discharges, minimum river elevation, water surface elevation, energy grade line elevation, velocity, flow area and top width of each cross section from about 14 km upstream of the overflow weir / ungated spillway to about 500 m downstream. In conclusion, this shows that there would be no major impact on upstream settlements due to the overflow weir at 2,414 m.a.s.l and flood would remain within the river system.

9.3 NATURAL DAMMING ON HUNZA RIVER

On January 4, 2010, a huge mass from the right bank of Hunza river slided down near Attabad village and blocked Hunza River for about 2 km. The inflow filled upstream valley created a 22 km long till reservoir the end of May 2010. The estimated lake initial storage was about 310 million m^3.

The deposited mass as a result of land slide is mainly composed of non-cohesive rock flour (fine dust, silt, silt gravels and cobbles) at the toe of the failed slope. Large boulders of granodioritic rocks with intrusions of granite, pegmatite and apatite were deposited close to the left bank of Hunza River. The deposit on the downstream side is composed of black clay with high plasticity and organic content. The upstream shoulder of the natural dam has mild slope and downstream slope is quite steep. With 2 km long dam, there is rare chance of piping failure.

A Dam brake study was conducted by NESPAK for National Disaster Mitigation Authority (NDMA) in March, 2010. For drainage of impounded flows through slided area, the excavation of material was proposed as 24 m deep and 45 m wide to form as spillway. The excavation works for the spillway was completed in the mid of May and the overflow began on May 29, 2010. The pattern of outflows was observed at downstream Ganish Bridge. The flows in summer 2010 were as a result of snow melt, no abrupt change in flows observed.

The recent deposits are the most widely spread soil units overlies the bed rocks. The slopes are covered with overburden having variable thickness. Terrace deposits comprise of mixtures of clay, sandy silt, boulders and gravel in various proportions. These units include Angular Boulder Gravel with Fines (ABGM), Rounded Boulder Gravel with Fines(RBGM), Terrace deposit and Moranic deposits. An overtopping concrete weir founded on slided mass is proposed after foundation treatment. Geological rock units with which weir has to be abut, includes Granodiorite, intruded by pegmatite veins at right side. On left side weir has to be abut with ABGM formed by slided mass.

The present bed level of Hunza River at start of narrow section downstream of reservoir is 2412 m.a.s.l. The river width is about 50 to 55 m in summer month. The water depth varies from 2 to 6 m depending upon the outflows. The existing water way would be remodeled to act as ungated spillway to pass the design flood. The river diversion during construction would be made through a low level open channel which would be used as sediment flushing channel during operation phase.

On the left bank of Hunza River, upstream of the weir, the river flows will be diverted at twin intakes into the power waterways system leading via desanders to the low pressure tunnel, surge tank, pressure pipe upto the power station from where the water ultimately discharges into the Hunza River. The roadway network exists at all important locations of proposed structures: weir, power intake, surge tank and powerhouse.

The maximum and minimum operating levels of the Attabad Lake Reservoir has been set by optimization and intake submergence requirements at 2414.0 m.a.s.l. and 2412.0 m.a.s.l. With normal poundage at 2414.0 m a s l, the length of reservoir is about 12 km and it has a gross capacity of 123 million m^3. The live storage with 2 m regulation from 2412 to 2414 m.a.s.l is 11 Million m^3.

The existing river course downstream of lake would be remodeled into channelized section. In the initial portion, a concrete structure of overflow weir / ungated spillway and stilling basin is proposed as control section for flood passage. Downstream of weir/spillway structure, trapezoidal section 50 m bed width. The overflow ungated weir/spillway crest is at 2414.0 m.a.s.l. On the left bank of main weir, a deep cut channel would be excavated to divert the river flows during construction for a discharge of 1750 m^3/s. The diversion channel later on would be used for sediment flushing. The width of flushing channel has been proposed as 25 m. Three

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

low level bottom outlets 5 m x 5 m are proposed to be equipped with hydraulically operated radial gates. Taking account freeboard above maximum flood level and gate operating of low level outlets and clearance requirements to pass flood, plate form level has been set at 2424.0 m.a.s.l.

A deep cut channel has been proposed on the left bank for diversion during construction which later on can be used for sediment flushing. The low level outlets can be used to supplement spillway discharge for additional measure of safety. The spillway discharges onto a stilling basin on the downstream for energy dissipation to be released into Hunza River. Considerable sediment inflow is expected into the reservoir during the glacier/snow melt runoff and also during rains. In order to maintain the power intakes free of sediment build up these are placed 2 m below the power intake. During the high flow season, the spillway will also be operated to pass any suspended sediment.

9.4 HYDRAULIC DESIGN

9.4.1 Hydraulic Design of Weir/Spillway and Stilling Basin

The weir/spillway overflow structure provided on the ALHPP is located on the left abutment of the embankment dam and is designed to safely pass the 1:10,000 year returned period flood of 3250m^3/s. The weir/spillway will be supplemented by the capacity of the three low level diversion cum flushing outlets in case of mal-operation of one gate and in case of emergencies.

Maximum reservoir level	2414.0 m.a.s.l.
Spillway crest elevation	2414.0 m.a.s.l.

9.4.1.1 Weir/Spillway Discharge Capacity Overflow Ungated Structure:

The weir/spillway structure was designed with a crest elevation of 2414.0 m a s l and a design head of 12.0 m. The spillway discharge capacity is calculated for various design discharges. The effect of piers and abutments on the effective crest width as well as the variation of the discharge coefficient with head are considered in the calculation of the spillway discharge capacity. For the relevant design floods the calculation of the discharge capacity has been performed and the corresponding results are given in the tables and graphs below.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

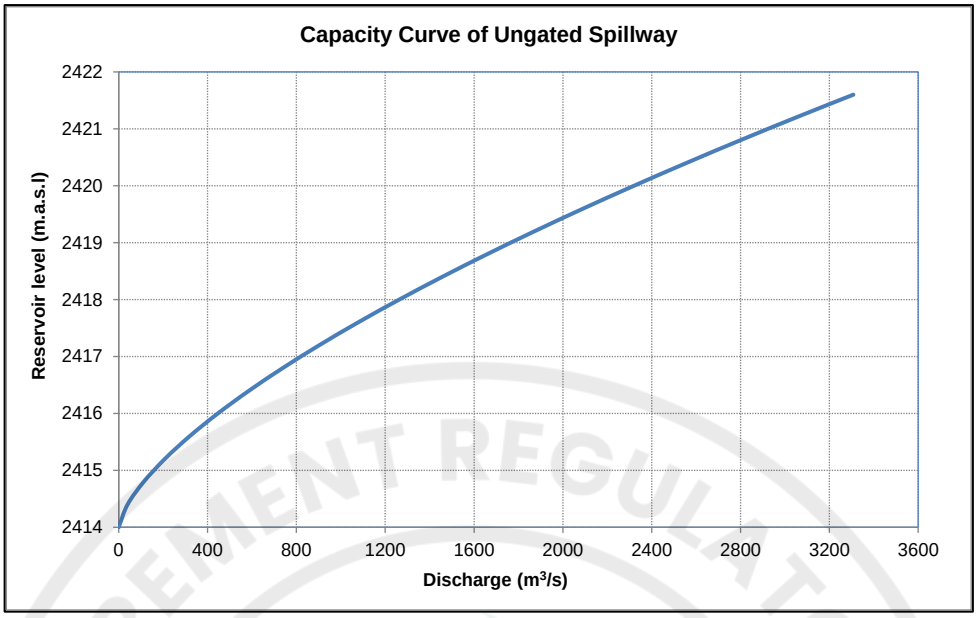

Figure 9-7 Discharge Capacity of Overflow Spillways

It is seen that the spillway discharge at elevation 2421.4 m a s l is 3,250 m^3/s. Along with overflow spillway, two low level flushing outlets would be in operation to discharge 600 m^3/s. The total discharge through overflow weir / ungated spillway is 3,250 m^3/s, which is 10,000 year return period. The spillway can therefore safely pass the PMF discharge with sufficient free board.

It is seen that the overflow weir/ungated spillway discharge capacity even at elevation 2414 m.a.s.l. is zero and spillage through power intake and sediment flushing outlet is possible which is only about 660 m^3/s when out of three, two under sluices are in operation. The discharge rating is shown in Figure 9-7 and indicates that the 1: 10,000 returned period flood can be passed safely in an emergency at an elevation of 2421.4 m.a.s.l.

9.4.1.2 Design of Spillway Stilling Basin

The riverbed downstream of the spillway consists of sandy gravels and boulders and would erode if the spillway discharges were released directly on to the bed. As such a stilling basin needs to be provided for energy dissipation.

The stilling basin is designed for the design flood of 1:10,000, (HQ 10,000 = 3,250 m^3/s). Proper functioning of the stilling basin is reconfirmed in addition for floods covering return periods from 1:10 to 1: 10,000 years AEP.

HQ_{10} = 2,040 m^3/s

HQ_{100} =2,910m^3/s

$HQ_{10,000}$ =3,250 m^3/s

The approach to hydraulic design of the stilling basin is as follows:

I. Determine the energy head at the spillway crest for the selected spillway design at maximum operation level of 2414.0 m.a.s.l.

II. Determine the hydraulic conditions along the ogee, in particular at the transition from ogee to stilling basin.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

III. Calculate the conjugated depth h2 of the hydraulic jump and the required length of the stilling basin.

IV. Determine the relevant tailwater level and calculate the required elevation of the stilling basin floor.

The relation between conjugate depths for a hydraulic jump on a stilling basin is given by,

$$\frac{h_2}{h_1} = \frac{1}{2}\sqrt{1 + 8F_1^2} - 1$$

Where,

h1 and h2 are the depths before and after the jump.

F1 is the Froude number at the start of the jump.

Tailwater levels has been checked for the various design discharges using the tailwater rating curve developed for the river cross-cross section 50 m downstream of the weir.

The hydraulic conditions from spillway crest to the stilling basin has been determined for discharges between HQ_{10} and HQ_{1000} i.e. 2040 to 3250 m^3/s. As a result, a stilling basin with the following dimensions have been selected:

Invert of stilling basin	2397.0 m.a.s.l.
Width of stilling basin	60.0 m.
Elevation of river bed d/s	2400.0 m.a.s.l.
Length of stilling basin	55.0 m.

Attabad Hydropower Project
Design Calculations for Weir

1. Weir Dimensions

Discharge (estimated design flood)	Q =	**3130**	m^3/s
Crest Width (as per site conditions)	B =	**60.0**	m
	B1 =	**60.0**	m
Gravity	g =	9.81	m/s^2
Crest Coefficient	μ =	0.9	

Water height over weir has been calculated from the formula as :

$$Q = 2/3 \mu B (2g)^{0.5} h^{1.5}$$

Height of Water above crest (from formula	h =	**7.33**	m
Upstream Bed Level (as per site condition)		2412	m
Weir Crest Level (assumed to pass flood)		2414.0	m
Water level at Flood (crest Elev.+h)		2421.3	m
Side Wall Level		2422.0	m

2. Design of Stilling Basin

Assumed Stilling Basin Level		2397		
Upstream water depth	h_o	9.33	m	
Inflow velocity	v_o	5.59	m/s	
Total energy at stilling Basin	E_o	25.91	m	
Height of weir	w	2.00	m	
Depth of water at toe (assume)	h_1	2.555	m	
Depth of water at toe (Calculated)	h_1	**2.539**	m	$h_1 = E_o - \frac{1.10 \times (Q^2)}{(h_1)^2 \times (B)^2 \times 2g}$
Velocity	v1	20.55	m/s	
Froud's number	F1	4.12		
Sequent Depth	h_u	6.40	m	
Velocity	V_u	8.15	m/s	
Depth of water after Jump	h_2	13.57	m	
Length of Stilling Basin	$5x(h_2-h_1)$	55.15	m	
Downstream water depth	h_d	6.00	m	
Level difference (e)	h_2-h_d	7.57	m

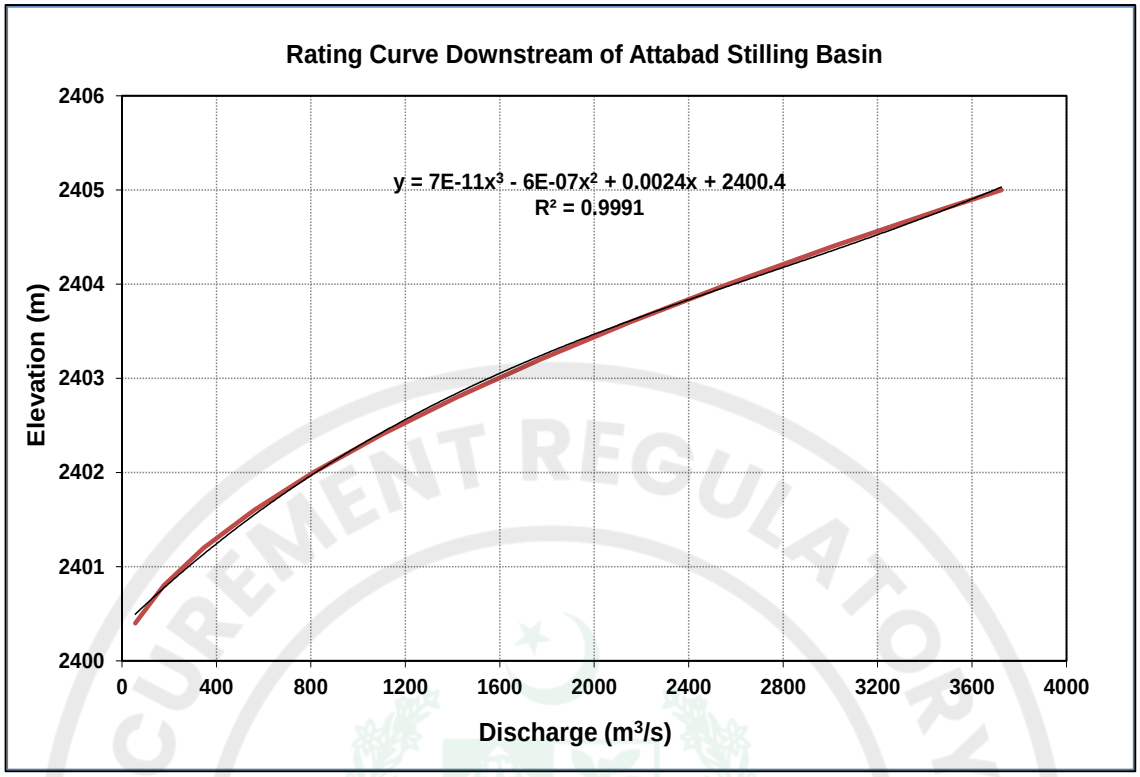

Figure 9-8 Tail Water Rating Curve Downstream of Stilling Basin

For the entire range of discharges considered in the present analysis, the criterion that the downstream water level exceeds the conjugated depth h_2 is maintained including a safety margin of 5 %.

Table 9-2 Variation of Stilling Basin Length with Flood Discharge

Discharge m^3/s	Flood	Energ Head m	Depth h_1 m	Froude number	Conjugate depth h_2 m	Tailwater level m.a.s.l	Stilling Floor m.a.s.l	Basin Length m
2040	HQ10	22.83	1.496	5.06	9.98	2403.5	2397	42.44
2650	HQ50	24.25	1.965	4.54	11.67	2404.1	2397	48.54
2910	HQ100	24.82	2.165	4.36	12.31	2404.3	2397	50.72
3730	HQ1000	25.91	2.539	4.12	13.57	2405.0	2397	55.15

9.4.2 Flushing Outlets

Three low level sediment flushing cum diversion outlets have been provided on the left bank upstream of the embankment dam to enable flushing of sediment in front of the power intakes. Each flushing outlet is equipped with a hydraulically operated slide gate as the service gate. Provision has been also made for installation of stoplogs both at the upstream and downstream ends of the tunnels for use both during maintenance and repair.

The flushing outlets will be utilized for the following:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Sediment flushing to keep the area upstream of the power intakes sediment free
- Reservoir (sediment) flushing in combination with reservoir draw down. The operational procedures for this need to be verified by physical model tests and also consider effects on reservoir periphery slope stability.
- For drawdown of the reservoir for maintenance and repair of structures as necessary.
- For use as an optional release facility for flood passage in the event of spillway gate problems.

The inverts of the flushing conduits have been set at riverbed level. The slide gates are located as upstream as possible in the conduits taking into consideration structural and operational requirements. Relatively high flow velocities will prevail and will prevent sediment load from depositing within the conduits. The design discharge capacity available at full reservoir supply level of 2414.0 m.a.s.l is 900 m^3/s with flushing outlets operating.

The flushing outlets are designed to be capable of removing fine and medium fractions of sediments (sand and gravel) that should not be allowed to accumulate in front of the power intake. During the high flow season 60 m^3/s will be diverted through the power intakes located upstream of the weir. The balance inflow may be released over the spillway and through the sediment flushing channel / undersluice, the latter being utilized to clear any sediment deposition in front of the intakes. This will ensure that coarse sediment fractions will not be drawn into the power intake at times of high river flow at normal operating level. No continuous flushing of the reservoir is envisaged. Discharge capacity of the two low level outlets which are also used as diversion tunnels during pre-commissioning stage for river diversion is provided in the details given under the sub-section on river diversion.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

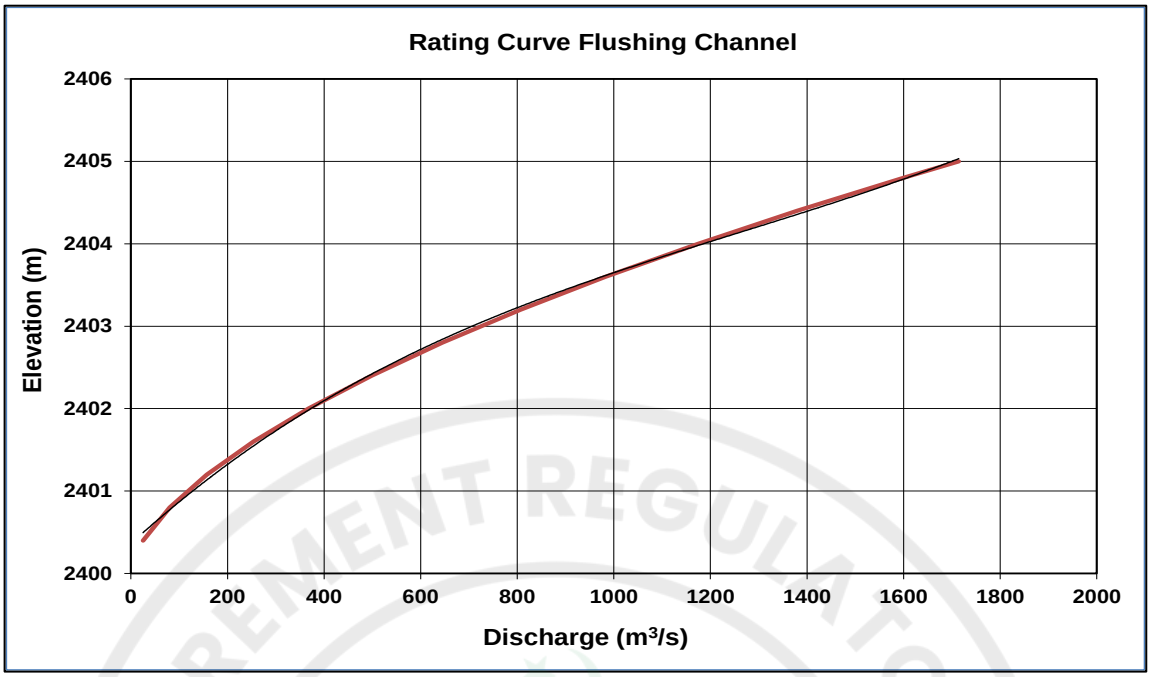

Figure 9-9 Tail Water Rating Curve at Flushing Channel

Reservoir drawdown can be achieved as when required through spillway and the low level outlets. However, it is necessary to ensure that the reservoir is not drawn down rapidly so as to provoke instability of the embankment dam or destabilize the reservoir periphery slopes. It is recommended that the hydraulic performance of the low level outlets be confirmed in combination with the spillway and power intake by hydraulic model tests at design stage.

9.4.3 Freeboard Calculations

Freeboard is provided on all dams to ensure that overtopping of the dam will not result from wind setup, wave action, uncertainties in analytical procedures and in operation in combination with high reservoir pool elevations.

Freeboard is the vertical distance between the crest of the dam and the reservoir water surface. Freeboard is further categorized into “normal freeboard” and “minimum freeboard”. Normal freeboard is the allowance between the crest of the dam and normal reservoir level as fixed by design. The normal freeboard should satisfy the dam safety needs for long term storage and must be adequate to prevent overtopping in case of abnormal and severe wind action of low probability that may result from unusual sustained winds of high velocity from a critical direction. Minimum freeboard is the difference in elevation between the crest of the dam and the maximum reservoir level that would result from the inflow design flood with normal spillway operation.

9.4.3.1 Wind Speed:

Wind speed at reservoir sites is best estimated from local measurements, although even these usually need to be carefully interpreted because of localized influences of surrounding topography. However, wind data was not available in the case of Attabad Lake weir stie. Therefore, in the absence of data, the per hour wind velocity over land has been assumed as per the recommendation of ACER Technical Memorandum No 2 (1992) which is 100 km/hr with all speed correction factors applied, for calculating minimum freeboard.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

9.4.3.2 Design Wave Height and Duration

The wave heights and periods are associated with the fetch. Wind duration and adjusted wind speed are determined from the ACER Technical Memorandum referred to above. Taking fetch length = 0.25 miles and wind velocity as 100 miles / hr. the wave height is 4 ft. (1.21m) for 4.5 seconds wave period. The duration of wind is 5 hours

Wave Height by Molitor – Stevenson Formula:

$$H_s = 0.76+0.032 (VF)^{0.5} -0.26 F^{0.25}$$

Where:

V = Wind velocity (km/h)	160
F = Fetch (km)	0.4
H_s	0.81 m

The maximum value of Hs = 1.21 m is adopted for design.

9.5 DESIGN OF RIVER DIVERSION WORKS

The riverbed at the weir site is about 60 m wide. On either bank, there is alluvium due to landslide and at rock is not found upto 68 m depth. The river diversion has been proposed in two stages. The river will flow through main weir section for constructing the left bank deep diversion channel regulated by gates after constructing a coffer dam in stage-I (shown in Dwg AFS-WE-412 in Vol.2) which will later used for sediment flushing channel. Afterwards a coffer dam has been constructed in stage-2 (detils shown in in Dwg AFS-WE-413 in Vol.2) and the river flow will be managed through diversion channel to construct the overflow weir/ spillway.

9.6 DISCHARGE CAPACITY OF RIVER DIVERSION WORKS

The magnitude of the construction flood is normally limited to flood return period of 1:20 to 1:50. However in the case of Attabad Lake, the diversion structures are designed for the average year flood of return period of 1:20 which is a flood of 1750 m^3/s magnitude. The risk of overtopping will be managed by strengthening of the coffer dam to tolerate overtopping during the construction period while the main embankment is still at lower levels.

The height of the upstream cofferdam has been estimated related to the discharge capacity of the diversion channel. The adopted crest elevation of the cofferdam is fixed at 2420.0 m.a.s.l. The channel will discharge in free flow condition.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 9-3 Diversion Channel Discharge Rating

Geometrical Input Data			Calculation of Downstream Rating Curve						
Length of Canal :	475.00	m	Wat. Dep.	Area	Wett.Par.	Hydr.Rad.	Discharge	Velocity	Froude No.

Discharge	**1857.79**	**m^3/s**	2.80	77.84	32.92	2.36	698.73	8.98	1.71
			3.20	90.24	34.05	2.65	874.02	9.69	1.73
WL Canal Start :	2403.00	m.a.s.l.	3.60	102.96	35.18	2.93	1065.38	10.35	1.74
WL Canal End :	**2397.00**	**m.a.s.l.**	4.00	116.00	36.31	3.19	1272.50	10.97	1.75
			4.40	129.36	37.45	3.45	1495.13	11.56	1.76
BL Canal Start :	2398.00	**m.a.s.l.**	4.80	143.04	38.58	3.71	1733.09	12.12	1.77
BL Canal End :	**2392.00**	**m.a.s.l.**	5.00	150.00	39.14	3.83	1857.79	12.39	1.77

The crest level of the coffer dam was set at elevation 2421.0 m.a.s.l. allowing about 2.0 m freeboard. The above results show that the adopted scale of the river diversion works accommodates reasonable risk from flooding during construction of the overflow weir / ungated spillway structure.

9.7 POWER INTAKE STRUCTURE

9.7.1 General

Twin intakes have been provided for intake of water into the power waterway system. The intakes are designed to be operated in such a manner as to ensure that the required turbine flow shall be conveyed within acceptable limit of head losses in accordance with the capacity requirements of the water conveyance systems and the power station in a safe and dynamically acceptable manner. The intakes will be capable of discharging the total design discharge for the generating units plus 20% of the design discharge for flushing the de-silting basin. The total design discharge of intakes is 60.0 m^3/s, that is, each intake will discharge 30.0 m^3/s. details of intake structure are shown in AFS-PI-424 to 426 in Vol.2.

On each structure, a trashrack has been provided at the entrance to prevent entry of debris into the power waterway system. The control gate in the gate passage is rectangular 4.5 m high by 3.6 m wide and is upstream sealing. This allows air passage downstream of the gate and does away with the need for special provision of an air vent. Provision has also been made for installation of stoplogs upstream of the control gates for maintenance and inspection. A

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

trashrack cleaning machine has been provided for removal of debris from the trashracks. A gantry has been provided for placement and removal of the stoplogs.

9.7.1.1 Siting and Orientation

The intakes have been sited on the left bank as close as possible to the embankment dam for mitigation of blockage by sedimentation, maximization of submergence and ease of flushing of sediment at the entrances by the low level flushing outlets cum diversion channel located just upstream of the embankment dam. The intake is oriented so as to minimize tendency for flow separation which can render a portion of the intake ineffective. Higher intake flow rates are more conducive to flow separation than lower rates and as such velocities of entry have been kept low.

The invert of the intake is placed at elevation 2412.0 m.a.s.l. based on sediment control and submergence considerations. Deck and other operating levels have been set at 2422.0 m.a.s.l.so that the intake can perform over a range of operating water levels in the reservoir including maximum flood water levels.

9.7.1.2 Intake Geometry

ALHPP intakes are low head, horizontal intakes. To minimize head losses and the potential for flow separation, the configuration of the entrance area of the intake is such that the flow accelerates more or less uniformly from the trashrack to the gate area and downstream.

Boundaries of flow approximate those of flow issuing from an orifice to minimize the effects of the surfaces on flow and thus minimize head losses. The boundary curvature upstream of the gates including roof, floor and sidewalls and those downstream of the gates including transition shapes and lengths are defined in accordance with the above considerations.

The entrance shapes are designed in accordance with guidelines given in U.S. Army Corps of Engineers EM 1110-2-1620 and the U.S. Army Corps of Engineers, Waterways Experiment Station (WES) Hydraulic Design Charts, HDC 221-2 or HDC 211-1 as suited to site lateral space availability.

9.7.2 Hydraulic Design

9.7.2.1 Criteria for Design

The following basic criteria shall be complied with in the hydraulic design of the intakes:

- The hydraulic performance of the intakes shall be sustained so that the net flow area on the intakes is not reduced by adverse sediment build up.
- The intakes shall be designed for hydraulically efficient flow with bell mouthed intakes and entrance losses shall be accounted for in the design.
- The intake shall have sufficient water cover under MDDL conditions and no vortices shall form. The design shall be tested by hydraulic model study and modified as necessary to prevent formation of vortices at detailed design stage.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Head losses in the waterway system shall be evaluated for hydraulic purposes and accounted for in design for all normal operating conditions.

- There shall be no settlement of sediment in the tunnel. Velocity in the tunnel shall be greater than the non-silting velocity at the design discharge of the tunnel.

- The water conductor system shall be designed to be emptied only by gravity.

- The intake gates shall operate only either in the fully open or fully closed position only. The gates shall be able to receive the command/signal from instruments and operate accordingly for this purpose.

- Provision will be made at the intake for instruments to collect and transfer information on gate positions, reservoir levels immediately upstream of the intakes, tunnel flows etc. for optimum operation of the Project.

9.7.2.2 Intake Submergence

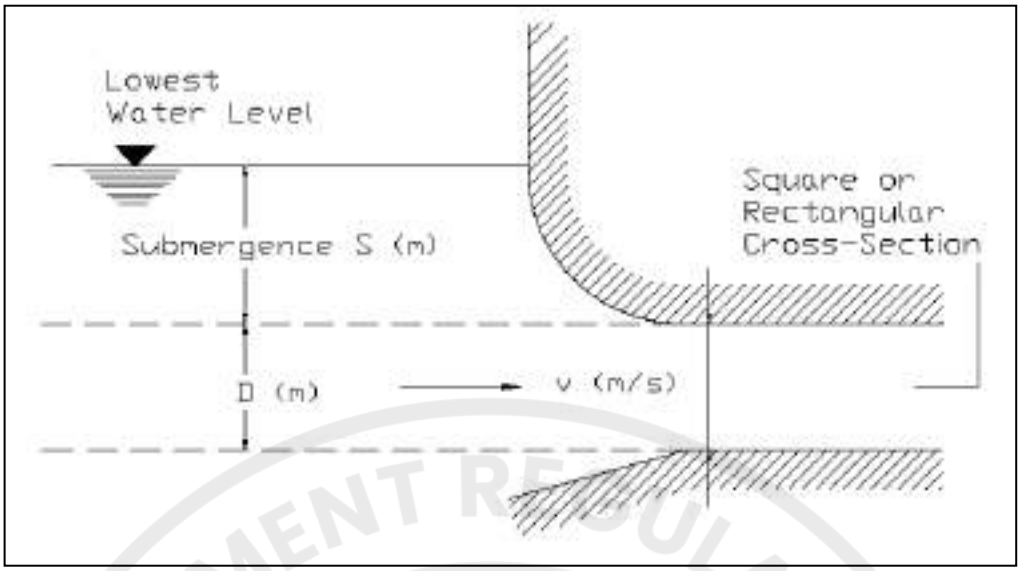
Vortices can affect intake efficiency and also present a safety hazard. The intensity of the circulation phenomena set up around an intake is a function of the geometry. Design guidance provided by Gordon and others shall be used in preventing formation of undesirable vortices. Gordon's curve for unsymmetrical flow is used for design.

Gordon's relationship for asymmetrical flow is given by:

$$S_{min} = 2.3\, DF_r$$

where

Fr = Froude number =V/$\sqrt{}$gD



V = velocity of flow in the conduit (m/s)

D = diameter or height of conduit (m)

S_{min} = required submergence from the opening soffit (m)

The power intakes should have sufficient submergence to prevent air entrainment by vortex formation. For the selected intakes each connecting tunnel design discharge is 60.0 m³/s.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

D = 4.5 m

V = 2.41 m/s

S_{min} = 2.3 x 4.5 x 0.36

S_{min} = 3.75 m

Take,

S_{min} = 3.75 m

9.7.3 Power Intake Settings

Maximum Operation Level	2414.0 m.a.s.l.
Minimum Operation Level	2412.0 m.a.s.l.
Required submergence	2.0 m
Intake waterway height	4.5 m
Required Invert level	2404.0 m.a.s.l.

The intake invert has been set at 2404.0 m.a.s.l.

Since vortex formation is dependent on many factors including orientation of the intake to flow and not only on submergence, hydraulic model studies are recommended at detailed design stage to confirm that vortices do not form at the intake.

9.7.4 Trashrack Cross-sectional Area

The gross cross-sectional area of the trashrack shall be selected for a flow velocity not exceeding 1.0 m/s. For the design discharge of 60 m^3/s, the required minimum trashrack area is determined as:

A_{min} required > Q / 1.0 m/s, giving Amin>60 m^2

Necessary trashrack area has been selected to comply with the above requirement with allowance for trashrack bar thicknesses etc.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

9.8 LOW PRESSURE TUNNEL

9.8.1 Criteria for design

The hydraulic design criteria followed for tunnels were as follows:

(i) Head Loss Considerations

For discharge calculation conservative values of loss coefficients have been taken in accordance with intake geometry and geometry of the tunnel. The approaches and flow boundaries are designed for hydraulically efficient flow minimize head losses.

(ii) Boundary Pressures

Pressure gradients are developed for the headrace tunnels to show local average pressure changes resulting from velocity changes. These are examined in terms of conduit back pressures for the entire operating range.

(iii) Air Relief

Air that occupies a partially filled tunnel can become trapped and can lead to operational difficulties such as head loss, unsteady flow, transients and blowouts. Air can enter the tunnel system at the intakes and at hydraulic jumps. It can also form when pressure and temperature conditions cause dissolved air to be released. Engineering measures are taken to reduce air entrainment which includes elimination of hydraulic jumps and dissipation of flow vortices at intakes. Vents to the ground surface are also given.

(iv) Flow Velocity

Flow velocities are restricted so that turbulent conditions and the possibility of damage to the structures are limited. Velocities for shorcrete lining shall in general be less than 3 m/s. For velocities greater than 3 m/s the risk of cavitation increases and special precautions like provision of concrete lining may need to be taken.

(v) Energy Losses

Energy losses within conduits fall into two general classifications: (a) surface resistance (friction) caused by shear between the confining boundaries and the fluid and (b) form resistance resulting from boundary alignment changes

(vi) Surface Resistance (Friction)

Three basic equations are generally being used for computing energy losses in pressurized systems. The Manning equation which has been used extensively for both free surface and pressure flow is adopted in this analysis.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Use of Manning's Formula

The Manning's Formula is expressed as:

$$V = \frac{S^{1/2} R^{2/3}}{n}$$

Where

R = A/P = Area of flow / Wetted perimeter

n = Manning's coefficient

S_o = Energy gradient Bed slope in uniform flow

(vii) Design Roughness Values

U.S. Army Corps of Engineers (EM 1110-2-2901) recommends the following values of Manning's n roughness values for different types of excavation and lining of tunnels:

USACE Recommended Manning's k Values

Type of Excavation or Lining	Recommended Manning's k Value
Drill and blast excavation, unhand	0.038
Tunnel boring machine excavation, unlined	0.018
Lined with pre-cast concrete segments	0.016
Lined with cast-in-place concrete	0.013
Lined with steel with mortar coat	0.014
Lined with steel (dia> 3 m)	0.013
Lined with steel (dia< 3 m (10 ft.))	0.012

However, the water conduit system was designed for Manning's k value of 0.016

(viii) Form Resistance

General

Energy losses caused by entrances, bends, gates, valves, piers, etc., are conventionally called "local losses". In many situations they are more important than the losses due to conduit friction. A convenient way of expressing the local losses in flow is,

$$h_l = K\,(V^2/2g)$$

Where

h_l = head loss in m

K = dimensionless coefficient

V = designated reference velocity m/s

g = acceleration due to gravity m/s^2

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The reference velocity in the energy loss equations corresponds to a local reference section of the conduit at or near the point where the loss occurs.

Sudden Expansion

In almost all cases the loss coefficient K is determined by experiment. However, one exception is the head loss for a sudden expansion. Designating the smaller upstream section as section one and the larger downstream conduit section as section two, the head loss equation may be written as:

$$h_l = (1 - A_1/A_2)^2 (V_1^2/2g) = K (V_1^2/2g)$$

In which

$$K = (1 - A_1/A_2)^2$$

Where A1 and A2 are the respective upstream and downstream conduit cross-sectional areas and the reference velocity is the upstream velocity V_1.

Sudden Contraction

The head loss h, due to a sudden contraction is subject to the same analysis as the sudden expansion, provided the amount of contraction of the jet is known. Using the downstream conduit velocity V_2 as the reference velocity, the head loss equation may be written as:

$$h_l = (1/C_c - 1)^2 (V_2^2/2g) = K (V_2^2/2g)$$

In which

$$K= (1/C_c - 1)^2$$

Where C_c is the contraction coefficient

(ix) Transitions

Head losses in transitions shall be calculated using the equation:

$$hl = K (V^2/2g)$$

where the value of the transition loss coefficient K must be obtained from published experimental literature or references.

(x) Bends

The bend loss, excluding friction loss, for a conduit is a function of the bend radius, conduit size and shape, and deflection angle of the bend. Bend loss coefficients K must be obtained from published experimental literature or references.

9.8.2 Low Pressure Headrace Tunnel

(i) Alignment of Headrace tunnel

Low pressure tunnel from intake to surge tank would be excavated in the left bank rock formation parallel and at lower elevation to existing Highway tunnel. The length of headrace tunnel is estimated about 2320 m.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

(ii) Dimensioning of Headrace Tunnel

Headrace tunnel was optimized by considering different diameters for design discharge of 60 m^3/s with following parameters:

- Manning- Strickler coefficient 60
- Tunnel slope 0.4 %
- Shotcrete lining thickness 0.10 – 0.3 m (as per conditions)
- Length of headrace tunnel 2300 m
- Diameter of concrete lined section 5.5 m
- Concrete Lining 0.3 m

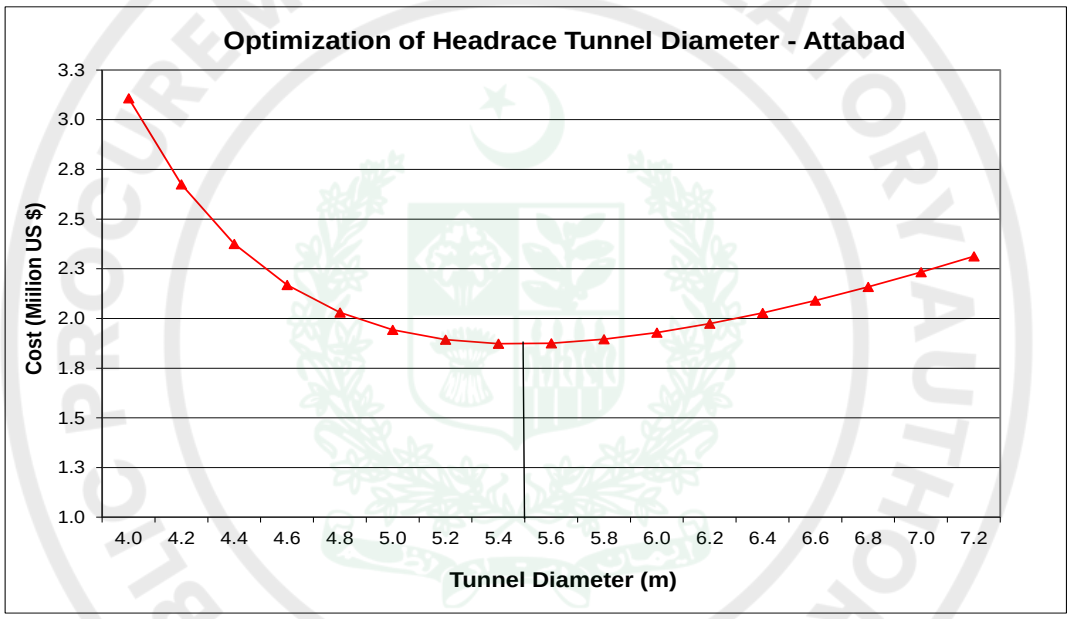


Figure 9-10 Optimization of Headrace Tunnel Diameter

The optimized diameter of low pressure headrace tunnel is 5.6 m and its length 2320 m. The alignment, layout and cross-sections drawings of low pressure headrace tunnel are given in AFS-WR-404 to 407 Vol. 2 Drawings.

9.9 SURGE TANK

The configuration of the waterway system has been generally given above and consists of two intakes with each intake connected to the low pressure headrace tunnel with an internal diameter of 5.5 m. The Surge tank is provided just before the start of pressure shaft. Downstream of the surge tank the headrace tunnel transitions from 5.5 m to 3.6 m diameter concrete lined section leading to embedded penstock. The penstock commences downstream of the surge tank with internal diameter of 3.5 m in the steel lined section.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

9.9.1 Hydraulic Design of Surge Tank

The principal surge tank designs considered Throttled cylindrical surge tank. At the junction of the headrace tunnel and surge tank a throttle with a cross-section area of not less than 50 % of the pressure shaft is arranged in accordance with standard design practice to damp pressure fluctuations. In view of the expected high flow velocities at the throttle it will be steel lined.

In accordance with standard design practice and the hydraulic design criteria, the cross sectional area of the cylindrical surge tank is selected with a factor of safety of 2.5 times larger than the Thoma-Criterion to ensure adequate stability of plant operation. Based on the characteristics of the upstream waterways and the design water levels, the minimum surge tank dimensions have been determined as shown in Table 9-4.

Table 9-4 Surge Tank Dimensions

Minimum Cross Section for Surge Tank at Headrace Tunnel			
Total headrace discharge	Q	60	m^3/s
Length of headrace tunnel	L	2320	m
Diameter of Tunnel	D	5.50	m
Cross section area	A	24.62	m^2
Head loss	h	2.6	m
Velocity in tunnel	v	2.46	m/s
Velocity head	$v^2/2g$	0.31	m
Minimum reservoir level	W_L	2412.0	m.a.s.l
Minimum tailwater level	W_L	2302.0	m.a.s.l
Head difference	H_o	110.0	m
Net head	H_n	105.2	m
	A_S	63.16	m^2
	1.5 A_S	90.08	
	$D_{Srequired}$	10.7	m
	$D_{Sselected}$	10.0	m

For load acceptance of the turbine units and subsequent full load rejection the following scenarios are assumed.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

LC-UP 1) Load acceptance from partial load, not exceeding 50 % total load increase; subsequent full load rejection;

LC-UP 2) Load acceptance of two units after synchronization; subsequent full load rejection;

LC-DN 1) Full load acceptance of two turbines followed by another turbine after a certain time interval

LC-DN 2) Load reduction by 50 per cent and subsequent complete load acceptance.

9.9.2 Load Case Maximum Upsurge

The load case is defined assuming that full load rejection occurs in the most unfavorable moment, i.e. when flow in the headrace tunnel is at its maximum (flow velocity) as the result of preceding partial load acceptance.

For the maximum upsurge analysis, the following assumptions are made:

Turbine load acceptance after synchronization	5.0 seconds (10 to100%)
Wicket gate closure at turbine load rejection :	5.0 seconds (100 to 0 %)
Maximum Reservoir Level :	2414.0 m.a.s.l.
Minimum tunnel roughness :	0.3 mm

The relevant load cases are defined assuming partial load acceptance following load rejection in the most unfavorable moment, i.e. when the flow in the headrace tunnel is at its maximum (reverse flow velocity) after full load rejection. A conservative approach is taken in the present feasibility design, full load acceptance of two units connected to the headrace tunnel will be assumed as extraordinary load case for which the surge tank design shall guarantee the specified minimum freeboard margins.

For the minimum down surge analysis the following assumptions are made:

Turbine load acceptance after synchronization	50 sec (10-100%)
Wicket gate closure at turbine load rejection	5.0 sec (100-0%)
Minimum reservoir water level	2412.0 m.a.s.l.
Maximum turbine discharge	20 m^3/s
Maximum tunnel roughness	0.3 mm

Minimum down surge was calculated for following scenarios:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

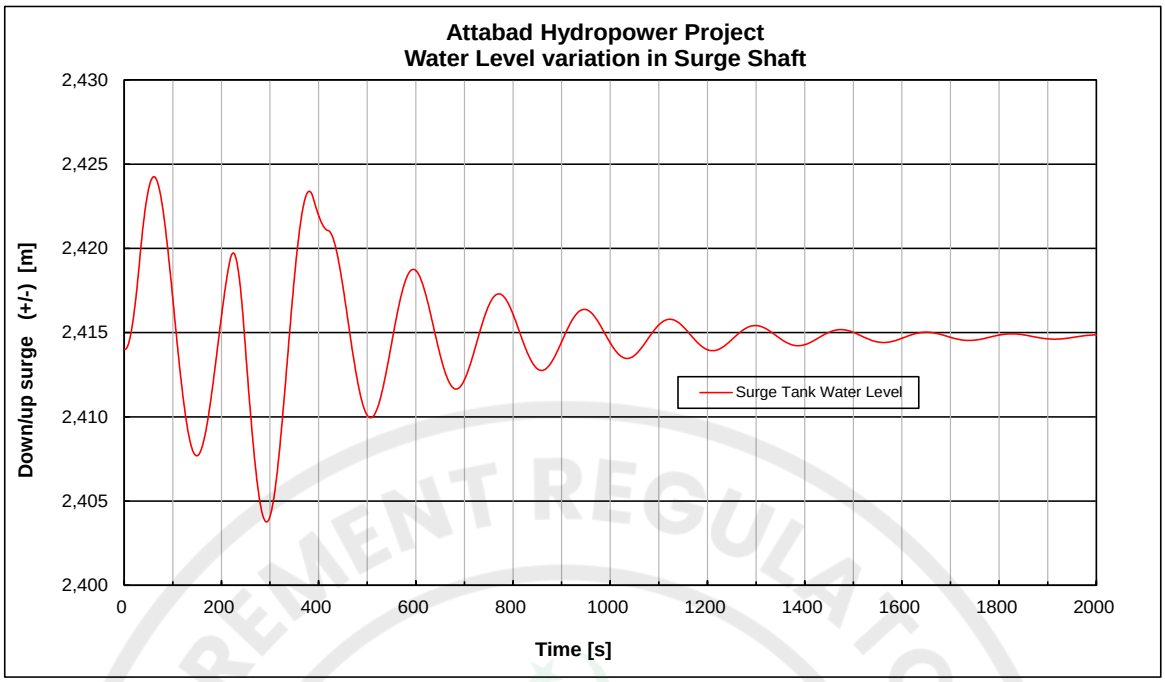

Figure 9-11 Surge Tank: Combined Load Case Maximum Upsurge

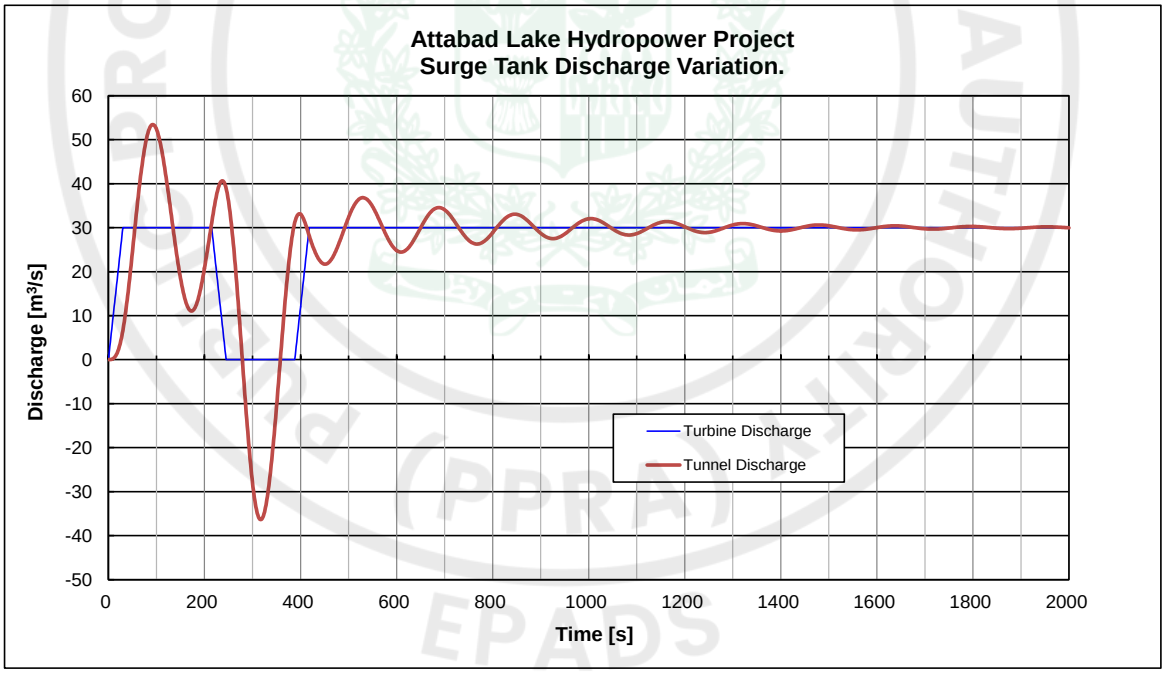

Figure 9-12 Surge Tank: Combined Load Maximum Upsurge and Downsurge

9.9.3 Results of Surge Tank Simulation

For the most critical load cases surge tank water level, flow into and out of surge tank and turbine discharge with time are shown in Figure 9-12.

For the load case resulting in the maximum down surge the corresponding variation of surge tank water level, is shown in Figure 9-13. The extreme surge tank water levels are given in Table 9-5 for all relevant load cases.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 9-5 Extreme Water Levels in Surge Tank

	Water Level
Upsurge	2424.2
Down surge	2403.8

9.10 WATER HAMMER ANALYSIS IN PENSTOCKS

For the calculation of pressure rise in the penstocks of Attabad Hydropower project water hammer analysis was carried out by applying the standard procedure based upon the following conditions:

Reservoir Level	2414.0 m.a.s.l.
Turbines centre line level	2300.0 m.a.s.l.
Operation Mode	Full Load Rejection within 5 seconds
QT for single unit	20.0 m^3/s

9.10.1 Water hammer calculations for single Penstock

In Attabad Hydropower Project the power house has three turbine units. Each turbine unit is connecting with one penstock. To calculate water hammer pressure in the penstocks the longest penstock is considered because it will give the maximum rise in pressure when valve of turbine closed suddenly. The longest penstock is 35m long.

Total discharge for 3 units	Q	= 60.0 m^3/s
Discharge for single turbine	QT	= 20.0 m^3/s
Diameter of penstock	D	= 2.07 m
Velocity in the penstock	V	= 5.89 m/s
Length of penstock	L	= 35 m
Maximum Operation Level		= 2414.0 m.a.s.l.
Minimum Tail Water Level		= 2300.0 m.a.s.l.
Maximum Head		= 114 m
Steel liner Thickness	t	= 25 mm
D/t		= 82.8

9.10.2 Pressure wave velocity

Engineering analysis of water hammer required the term a which is the velocity of pressure wave. According to Parmakian (1955) the velocity of pressure wave is given by the following formula:

$$a = \sqrt{\frac{1}{\rho(\frac{1}{K} + \frac{DC_1}{Et})}}$$

Where

E = Elastic modulus for steel = $1x10^9$ N/m^2

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

K = Volume modulus of water = 2.1×10^{11} N/m^2

ρ = Mass of water = 1000 kg/m^3

$C_1 = 1-u^2$

u = Poisson's ratio for steel = 0.3

a = 140 m/s

9.10.3 Water hammer Pressure (Allievi chart)

Neglecting hydraulic losses in the Penstock,

Pipe-line constant, $\rho = \frac{aV}{2gH_o} = 0.2267$

For closure time t = 5sec

Time constant, $\theta = \frac{aT}{2L} = 10$

From Allievi Chart,

Max. Pressure rise ratio, $Z = \frac{H_o + h_{\max}}{H_o} = 1.025$

$H_O + h_{max} = 1.025 H_o = 107.6$ m

Hence pressure rise in penstocks for sudden closure of value (5s) the pressure rise in 35 m long penstock is 33.02 m.

9.11 POWER COMPLEX

9.11.1 General

At the powerhouse site mildly sloping terrace with good geological conditions is available to place a surface power complex. Hence a surface power complex is selected. The power complex comprises of mainly surface powerhouse, transformers bay and Gas Insulated Switchgears (GIS) building.

The powerhouse building houses three (03) Francis turbine units each comprising main inlet valve. The vertical axis Francis turbine is coupled directly to a generator, their auxiliary plant, the generator circuit breakers, isolators and unit transformers. The powerhouse also accommodates the main drainage sump, battery rooms, mechanical and electrical workshops.

The transformer bay houses 10 transformers (three each for a unit) and one spare transformer, a rail is provided beside the transformers for gantry crane to move along 6 m. wide roadway. The general arrangement of the power complex structures are shown in Dwgs. No. AFS-PH-431 to 436 in Vol. 2 Drawings

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

9.11.2 Sizing of Powerhouse

The powerhouse building was sized considering the turbine axis setting level and space required to house the electrical equipment, transformers and mechanical plant with adequate allowance for installation, operation and maintenance.

Floor levels in the machine hall are dictated by the level of the turbine centerline which is set at elevation 2308.0 m.a.s.l. The water after passing through Francis pressure turbine goes into elbow shaped draft tube and carried out to tail bay from where the open free flow tailrace channel starts. The outlet of the draft tube will always remain submerged to avoid suction. The submergence height with reference to turbine centreline is calculated as 4.5 m by Thoma criteria. With the submergence height the minimum tailwater level is fixed at elevation 2300.0 m.a.s.l. and the maximum Tailwater is at elevation 2307.0 m.a.s.l. A draft tube gate is provided at its outlet which is to be operated by a gantry crane to be placed at elevation 2308.2 m.a.s.l.

The turbine, electrical equipment, generator and operating floor levels are determined chiefly by the headroom required to access the turbine pit with the top cover suspended, the headroom to accommodate auxiliary equipment such as the generator circuit breakers, the structural depth of concrete to carry the bottom bracket, and the height of the generator.

Placing the crane rail level, the underside of the crane bridge beam and the main hook height around 5.80m from the operating floor which at elevation 2306.2m.a.s.l. should allow cranes in tandem, utilizing a lifting beam about 2m deep, to lift either the rotor or the stator to a height safely above the generator exciter housings, usually standing about 1 m above the floor. A sloping trussed roof is proposed to cater for the snow accumulation problem over the roof. Minimum of 2.5 m clear height is provided over the top of crane bridge beam which at the centre is 6.0 m which is sufficient for movement of operating and maintenance staff.

All levels will be confirmed or revised if necessary when turbine and generator manufacturer's data is received during detailed design. Manifold will be constructed for the trifurcating the 4.2 m dia. steel lined high pressure tunnel into three 1.85 m dia, penstock pipes that will be connected with spherical valve and further leading to turbine.

The surface powerhouse building is 63 m long, 20 m wide and 35 m high from the foundation level. At the draft tube end a draft tube gate is provided which will be lifted by a gantry crane moving on 3.2 m extended cantilevered deck along each unit bay.

9.11.3 Powerhouse Building

The powerhouse building comprises of the four main floors which are:

- Machine Hall floor at Elevation. 2306.2 m a s l
- Generator floor at Elevation. 2303.0 m a s l
- Turbine floor at Elevation. 2298.0 m a s l
- Valve floor at Elevation. 2300.0 m a s l

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

In addition to these floors the following are full width but shorter floors provided at different levels such as:

- Administration Floor at Elevation. 2306.2 m a s l
- Services and HVAC floor at Elevation. 2309.2 m a s l

Machine hall floor is divided into three sections i.e. Erection bay, Unit bays and powerhouse Operation bay. Erection bay is provided between the main access and the machine bay. The length of this bay is 11 m that will allow the assembly, erection and dismantling of one complete machine, providing adequate floor space for assembling the bottom cover, runner, top cover, shaft, bottom bracket, rotor and top bracket. The unit bays length is 10.0 m and it comprises of three units. The control room, store, lift, stairs and amenities are located in powerhouse operation bay. From machine hall floor three cable ways from generators lead to transformers bay which is of the same level of machine hall i.e. 2009.0 m. From transformers cable galley carries cables to GIS switchyard for further transmission.

On Generator floor, in addition to three generators, mechanical, electrical workshops, welding room and store are provided under the erection bay. Beyond the unit bays battery and charger rooms are placed along with lift and stairs. Turbine floor houses three turbine units and on one side there are compressor room with lift and stairs. On Valve floor spherical valves are placed on pedestals. The length of this floor is approx. 48 m. Stairs are terminated at this floor. Below this floor there are drainage and cooling water pits. The drainage sumps have emergency pumps.

On Administration floor meeting room, prayer room, offices, stairs and lift are provided. Services and HVAC floor contains potable water, service water, HVAC plant room with treatment, etc. Two overhead cranes run in the powerhouse building at Elevation. 2012.0 m. The powerhouse building floor plans and cross sections are given in Dwg. No. AFS-PH-431 to 436 in **Vol. 2 Drawings.**

9.12 TAILRACE CHANNEL

From each turbine the water will be carried through elbow shaped draft tube that will outflow into a tailrace bay from where the tailrace channel starts. The design parameters of the tailrace channel are as follows:

Type	Concrete lined
Manning Stickler’s coefficient	60
Total Length	18.0 m
Cross section type	Rectangular
Width	45.0 m
Height	13.0 m to 10.0 m

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

10 GEOTECHNICAL & STRUCTURAL STABILITY ANALYSIS

10.1 GENERAL

The overflow weir/ungated spillway and sediment flushing channel/undersluice of the Attabad Lake Hydropower Project (ALHPP) are in between sloping surfaces on both the left and right banks of existing spilling channel of Attabad Lake. Major focus of geotechnical and structural stability is carried out for an overflow weir/ungated spillway and sediment flushing channel/under sluices located on or near sloping ground, and thus are potentially subject to various kinds of slope instability such as slides, flows and falls. Slope failures can produce extensive damage to the structure. Therefore, it is necessary to evaluate the proposed slopes to assess their stability.

Slope geometry is an important factor which affects the slope stability. The basic geometrical slope design parameters are bench height, overall slope angle, and surface area Stability of slope decreases with the increase in its height and slope angle. In case of the ALHPP, for the sake of stability the slope is cut and is proceeded from top towards the edges of the structures in bench formation.

The cross sections showing benched slope stability options are shown from AFS-WR-414 to 423 Vol.2 Drawings. The cross section selected for analysis is the critical section at Chainage 0+50, where the main structure of the Project is placed in between the two slopes; the left slope will be benched from El 2490 to 2400 m.a.s.l, which needs analysis for its safety.

10.2 PROJECT NARRATIVE FOR USE OF GEOTECHNICAL SOFTWARE (SLOPE-W; GEOSTUDIO)

Manual procedures available for slope stability analysis are very laborious. These have limited application and based upon various assumptions. Quite often, the manual procedures for slope stability are very complex and less precise.

Over the last five decades, a lot of research has been carried out in the world for developing new techniques for planning, analysis and design. In this regard, various techniques have been developed to produce better quality of analysis in civil engineering projects. Besides, these techniques are being supplemented by computer software which save a lot of time and effort and thus provide better quality and cost effective design by incorporating actual conditions at the site. Use of computer software have made it possible to incorporate those analysis conditions which were limited in the past owing to tedious manual methods of analysis.

SLOPE/W provides less tedious and user-friendly operation and also reflects the existing conditions at the Project Site and operates in Windows Environment.

The analysis on geotechnical software is intended to provide guidance for the proper procedure and incorporation of modern techniques for stability analysis for sound design, saving the efforts involved in conventional analysis. The cross section showing slope under analysis is shown in **Figure 10.1.**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Figure 10-1: Cross Section at Chainage 0+50

10.3 GEOLOGY OF THE SLOPES

Slided mass covers huge volume and consisted of mixed boulders and gravels near the slope surface and beneath the proposed area of overflow weir/ungated spillway and sediment flushing channel/undersluice. One of the difficult and critical task is to stabilize the both side slopes along the weir and sediment flushing channel. Benching is one of the best solution for such type of slope to stabilize. At some place, mashing or gabion maybe helpful for slope stabilization.

10.4 SCOPE OF THE ANALYSIS

The intended scope of the design has been to analyze the critical slopes near ALHPP structures, using conventional (computer aided) methods of analysis. The comparison of results obtained by different analysis methods is presented in factors of safety.

10.5 DESCRIPTION OF THE SLOPE STABILITY ANALYSIS

The conventional methods of slope stability analysis used are based on limit design. In these methods a trial surface of sliding is assumed and a quantitative estimate of the factor of safety is obtained by considering the overall equilibrium of the sliding mass and comparing the strength necessary to maintain limit equilibrium with the available shear strength of the embankment material. Stability computations are performed along a number of sliding surfaces to obtain the minimum factor of safety. The sliding surface, along which the minimum factor of safety is obtained, is known as the critical sliding or slip surface.

The basic premise of all limit equilibrium methods of stability analysis is that the slope mass acts as a rigid body and the shear strength of the materials will be fully developed at all points simultaneously along a surface of incipient failure. Deformations of the slope mass and the relationships of the strain to the developed strength of the material are not accounted for in the analysis as customarily performed. Such assumptions are significant departures from reality and the magnitude of the error involved will depend on the stress-strain relationships of the materials involved. However, limit equilibrium methods are used because of their simplicity and

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

the fact that experience has shown that if the factor of safety exceeds the recommended value, the slopes would be safe against shear failure and would not suffer excessive deformations.

The shape of sliding surface depends on the geometry of the problem and may be circular or non-circular. A shear failure in a steep slope of homogeneous soil will usually develop along circular surfaces; however, if weak layers or seams are present in the soil profile, the failure surface will have a tendency to follow these planes, insofar as kinematically possible, and adopt a non-circular shape. In most cases the sliding surfaces can be approximated by circular slip surfaces even for non-homogeneous (zoned) sections with moderate differences in the shear strength of constituent materials.

These methods are described in detail in the following sections:

10.5.1 Ordinary Method of Slices

In all the limit-equilibrium methods of stability analysis the factor of safety is determined by considering equilibrium of the potential sliding mass along assumed slip surfaces and locating by trial the slip surface that gives the lowest factor of safety. The method of analysis should be such as to accommodate conditions wherein the slip surface is curbed and the soil properties and pore pressures vary with location through the slope. For this reason, most of the equilibrium methods divide the free-body bound by the slip surface into a number of vertical slices. This procedure is known as the method of slices and is adaptable to any type of slip surface, circular or curbed. The method was pioneered by Fellenius and Taylor and has since been developed to improve its reliability and accuracy.

Equilibrium Requirements

In this method the potential sliding mass is subdivided into a number of vertical elements or slices. These slices need not be equal in width, e.g., slice widths may be selected in such a way that, as far as possible, the base of each slice falls within one type of soil in a non-homogeneous slope. The inclination of the base of each slice, the slice weight, the material properties and the pore pressures at the base of each slice should be known before an analysis can be carried out.

Figure 10.2 shows a potential sliding mass along a trial slip surface through an embankment slope. The sliding mass is subdivided into a number of imaginary vertical slices. Usually six to nine slices are adequate for all practical purposes. The ratio between slice height and slice width should usually be 1 to 2.5, or maximum 3.

Each slice is acted upon by its own weight W and by the boundary interslice or side forces, both of which have tangential or shear components X and normal components E. The forces acting on the base of the slice are the shear resistance S and the normal force P. A rigorous solution to the problem of stability involving the soil mass would require that:

- The forces on each slice must satisfy the conditions of equilibrium, and
- The forces acting on the sliding mass as a whole must satisfy conditions of equilibrium.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The following static equilibrium conditions should be satisfied:

- Sum of all vertical forces, $\sum F_V = 0$
- Sum of all horizontal forces, $\sum F_H = 0$
- Sum of moments of all forces about any point, $\sum M = 0$

These conditions should be satisfied both for the individual slices as well as for the overall equilibrium of the slope.

In addition, to enable computation of the factor of safety, the following equation relating the equilibrium shear stress to the shear strength of the material is introduced. A state of limiting equilibrium is said to exist when the equilibrium shear stress is express as:

$$\tau = \frac{\tau_f}{F}$$

Where,

F = Factor of safety;

τ_f =Shear strength at failure

τ = Equilibrium shear stress along the shear surface

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

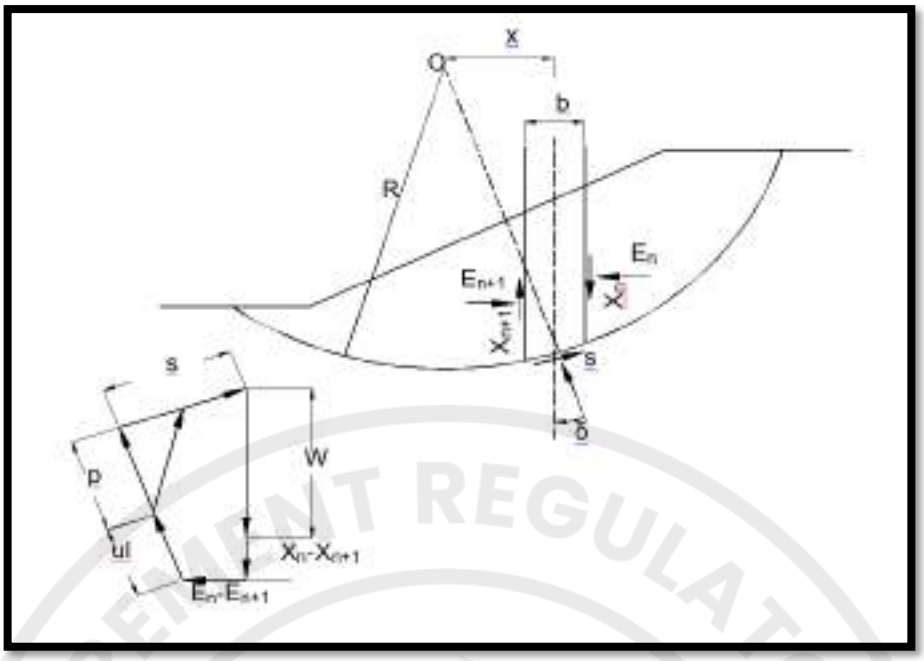

Figure 10-2: Sliding Mass – ordinary method of Slices

The shear strength of soils is usually expressed by Coulomb's equation:

$$\tau_f = c' + \sigma'_n \tan\phi'$$

Combining eqns. above,

$$\tau_f = \frac{c'}{F} + \frac{\sigma'_n \phi'}{F}$$

$$\tau = c_e + \sigma'_n \tan\phi_e$$

Where 'c' and 'phi' are the mobilized or developed values of shear parameters corresponding to equilibrium shear stress acting along the shear surface.

Limit equilibrium analysis is based on the assumption of ideal plastic behavior wherein stress-strain relationships do not exist (as for brittle soils) and the shear stress is defined by eqn. 2.3, the term 1/F giving the degree of mobilization. Implicit in the analysis is a constant value of F along the entire shear surface. Most soils lie somewhere between the ideal brittle and plastic materials.

By using the factor of safety to define the limit equilibrium, one can easily discriminate between the failure shear surface (F_{min} = 1) and the critical shear surface at equilibrium (F_{min} > 1).

Limitations of this method

The number of unknowns (interslice forces, normal and tangential forces, and F) are more than the number of equations. No explicit solution is therefore possible for the factor of safety, and it is necessary to make further simplifying assumptions to arrive at a solution. The various

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

procedures of stability analysis differ principally in the equilibrium requirements they satisfy and the manner in which they handle the interslice forces.

10.5.2 Bishop method of Slices

The Simplified Bishop Method satisfies the following two equilibrium conditions:

XI. Overall moment equilibrium about the centre of the slip surface;

$$F = \frac{1}{\sum W \sin\alpha} \sum [c'l + (P - ul)\tan\phi']$$

XII. Vertical equilibrium for each slice; thus resolving the forces acting on a typical slice vertically (Figure 10.2).

$$W + X_n - X_{n+1} = P\cos\alpha + S\sin\alpha$$

The factor of safety in this method is computed by the equation:

$$F = \frac{1}{\sum W \sin\alpha} \sum [c'b + \tan\phi'(W - bu + X_n - X_{n+1})] \frac{1}{m_\alpha}$$

It is assumed in the Simplified Bishop Method that the interslice forces are adequately defined by their horizontal components and their vertical components can be neglected. With this assumption, the final factor of safety equation will be:

$$F = \frac{1}{\sum W \sin\alpha} \left[\frac{c'b + \tan\phi'(W - bu)}{m_a} \right]$$

Limitations of this method

The main limitations of the Simplified Bishop Method are that it neglects the vertical component of the interslice forces and does not satisfy the horizontal force equilibrium. In practice, the Simplified Bishop Method has proved an accurate method for circular slip surfaces, including flat slopes with high pore pressures, and has gained wide acceptance. The justification for using the Simplified Bishop Method is largely empirical.

10.5.3 Spencer method

Keeping in view the limitations of the above methods used, spencer method is also used which produces accurate values of FOS keeping by considering also the following:

- Considers both shear and normal interslice forces,
- Satisfies both moment and force equilibrium, and
- Assumes a constant interslice force function.

The force-equilibrium factor of safety F_t can be obtained by the following:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

$$F_t = \frac{\sum\left[\{c'b + \tan\phi'(W - bu + X_n - X_{n+1})\}\frac{1}{m_\alpha}\sec\alpha\right]}{\sum[W + X_n - X_{n+1}]\tan\alpha}$$

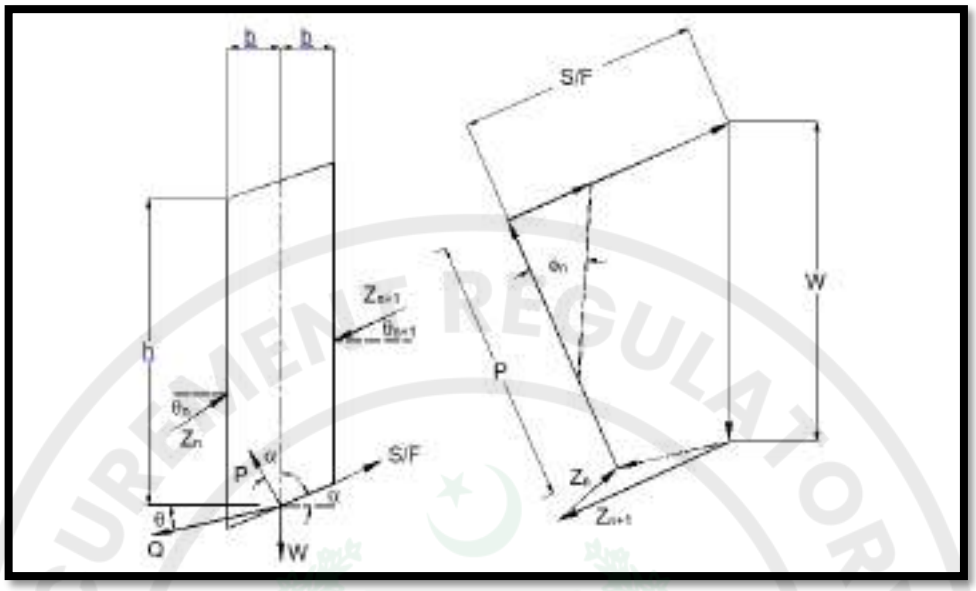

Figure 10-3: Slice Orientation – Spencer Method

When using Spencer's Method for analyzing slope stability for a non-circular sliding surface, the moment-equilibrium equation can be established by taking moments of the forces acting on the slices about some arbitrary center of rotation. The rest of the procedure remains unchanged.

10.5.4 Janbu Method

Janbu's Method of stability analysis, also known as the Generalised Procedure of Slices (GPS), can be used for solving stability problems involving a shear surface of any shape, circular or curved. Janbu considered the force and moment equilibrium of an individual slice as well as the equilibrium of the sliding mass as a whole. In view of the difficulty of obtaining a moment-equilibrium equation for the sliding mass as a whole for a non-circular sliding surface.

10.5.5 Morgenstern-Price method

Morgenstern and Price (1965) developed a method similar to the Spencer method, but they allowed for various user-specified interslice force functions. The interslice functions available in SLOPE/W for use with the Morgenstern-Price (M-P) method are:

- Constant
- Half-sine
- Clipped-sine
- Trapezoidal
- Data-point specified

Selecting the Constant function makes the M-P method identical to the Spencer method.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

10.6 PROS AND CONS OF SLOPE STABILITY METHODS-SUMMARY

Many different solution techniques for the method of slices have been developed over the years. Basically, all are very similar. The differences between the methods are depending on: what equations of statics are included and satisfied and which interslice forces are included and what is the assumed relationship between the interslice shear and normal forces?

In the beginning, Ordinary, or Fellenius method was first developed. The method ignored all interslice forces and satisfied only moment equilibrium. These simplified assumptions made it possible to compute a factor of safety using hand calculations, which was important since there were no computers available.

Later Bishop (1955) devised a scheme that included interslice normal forces, but ignored the interslice shear forces. Again, Bishop's Simplified method satisfies only moment equilibrium. Of interest and significance with this method is the fact that by including the normal interslice forces, the factor of safety equation became nonlinear and an iterative procedure was required to calculate the factor of safety.

The Janbu's Simplified method is similar to the Bishop's Simplified method. It includes the normal interslice forces and ignores the interslice shear forces. The difference between the Bishop's Simplified and Janbu's Simplified methods is that the Janbu's Simplified method satisfies only horizontal force equilibrium, as opposed to moment equilibrium.

Later, computers made it possible to more readily handle the iterative procedures inherent in the limit equilibrium method, and this lead to mathematically more rigorous formulations which include all interslice forces and satisfy all equations of statics. Two such methods are the Morgenstern-Price and Spencer.

10.7 SLOPE STABILITY INPUT PARAMETERS

The parameters are used are as follows:

Above below Water Surface:

- c 100 KPa
- Phi 20
- Unit Weight 21 KN/m^3

Above Water Surface:

- c 120 KPa
- Phi 25
- Unit Weight 18 KN/m^3

Youngs Modulus of Elasticity is 1.29 e +4 and poisons ratio used is 0.15

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

10.8 METHODOLOGY ADOPTED FOR SLOPE STABILITY SLOPE/ W ANALYSIS

Slope stability analysis of critical slope at ALHPP is done by using aforementioned methods for the following two different slip surface arrangements within the Slope/ W software:

- Grid and radius Arrangement of Slip Surfaces
- Entry and Exit Slip Circle arrangement.

The Factor of Safety (FOS) has been calculated by introducing 2000 iterations and a Critical Slip Circle (the slip circle whose FOS is the minimum) has been found by analysis.

The shear strength & Normal Strengths and Interslice forces are drawn for each of the slice.

The Analysis are shown in **Figure 2-1 to Figure 2-10 (Volume 7 Appendices)**.

The Results from the analysis are tabulated in **Table 10-1 below**:

Table 10-1 Results of SLOPE/W Methods

Method	**Grid & Radius arrangement for Slip Circle**	**Exit and Entry Arrangement for Slip Circle**
Ordinary or Fellenius	**1.75**	**1.53**
Bishop's Simplified	**1.865**	**1.63**
Janbu	**1.725**	**1.51**
Spencer	**1.87**	**1.62**
Morgenstern-Price	**1.821**	**1.63**

10.9 CONCLUSIONS FOR SLOPE STABILITY SLOPE/ W ANALYSIS

The stability analyses of critical slope at Chainage 0+50 is analyzed under different loading conditions using conventional methods of analysis revealed that Spencer Method and Morgenstern-price Method (which satisfies only force and Moment equilibrium both) normally gives the highest factors of safety while Janbu Method (gives the lowest factor of safety). The variation among the methods is upto 9%.

Morgenstern Price method and spencer's method of analysis gave the identical results in the analyses this is owing to the fact that both the methods satisfy force as well as normal equilibrium.

FOS is inversely proportional to the height of the slope.

Material used on the facing with higher value of cohesion will increase the factor of safety.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Following general findings have been deduced for all the methods in terms of equilibriums:

Method	Moment Equilibrium	Force Equilibrium	Interslice Normal (E)	Interslice Shear (X)
Ordinary or Fellenius	Yes	No	No	No
Bishop's Simplified	Yes	No	Yes	No
Janbu's Simplified	No	Yes	Yes	No
Spencer	Yes	Yes	Yes	Yes
Morgenstern-Price	Yes	Yes	Yes	Yes

10.10 FUTURE RECOMMENDATION

For future, if there is possibility of water filled tension crack upstream of slopes, causing the slopes to be saturated it is proposed to carry out the study on same lines using dynamic deformations. In this way it will be possible to calculate pore pressure changes effecting FOS of the whole system/ slope. This may be carried out using another computer software QUAKE/W in association with SLOPE/W.

10.11 GEOTECHNICAL STABILITY OF OVERFLOW WEIR/UNGATED SPILLWAY STRUCTURE WITH RESPECT TO SEEPAGE FORCES

10.11.1 Seepage Analysis

The objective of the analysis in case of an overflow weir/ungated spillway structure is to determine the following parameters which will be used in various stability checks:

- Total head dissipation from u/s to d/s.
- The Pressure Head and Pressure Profiles.
- The Hydraulic xy- Gradient Profiles
- Computation of Critical Hydraulic Gradient at d/s.
- Safety against Uplift
- Safety Against Piping

Seepage analysis is done to analyze whether the structure is safe against uplift and piping with respect to highest flood level and normal level conditions.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Seepage analysis is done by using Finite Element Analysis technique. The SEEP/W in GEOSTUDIO software used for the analysis. SEEP/W basically obeys the flow law described hereafter.

10.11.2 Flow Law

SEEP/W is formulated on the basis that the flow of water through both saturated and unsaturated soil follows Darcy's Law which states that:

$$q = ki$$

Where;

$q =$ Specific discharge

$k =$ Hydraulic conductivity

$i =$ Gradient of fluid head or potential

Darcy's Law was originally derived for saturated soil, but later research has shown that it can also be applied to the flow of water through unsaturated soil. The only difference is that under conditions of unsaturated flow the hydraulic conductivity is no longer a constant but varies with changes in water content and indirectly varies with changes in pore water pressure.

Darcy's Law is often written as:

$$v = ki$$

Where v is known as the Darcian velocity. The actual average velocity at which water moves through the soil is the Darcian velocity divided by the porosity of the soil. SEEP/W computes and presents only the Darcian velocity.

10.11.3 Governing Equation of Seepage Analysis

$$\frac{\partial}{\partial x}\left[k_x \frac{\partial H}{\partial x}\right] + \frac{\partial}{\partial y}\left[k_y \frac{\partial H}{\partial y}\right] + Q = m_w \gamma_w \frac{\partial H}{\partial t}$$

Where;

$k_x =$ Hydraulic conductivity in the x-direction

$k_y =$ Hydraulic conductivity in the y-direction

$H =$ Total Hydraulic Head

$Q =$ Applied boundary flux

$m_w =$ Slope of the storage curve

$\gamma_w =$ Unit weight of water

10.11.4 Geology at Overflow Weir/Ungated Spillway

An overtopping concrete weir founded on slided mass is proposed after foundation treatment. Geological rock units with which weir has to be abut, includes granodiorite, intruded by

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

pegmatite veins at right side. On left side, weir has to be abut with Angular Boulder Gravel and Fines (ABGM) formed by slided mass (Vol-2, AFS-GE-297). As described in Volume 3 Geology and geotechnical studies, some treatment / engineering solution have to be implemented for stability of the weir and its left abutment. The basic purpose is to provide seepage line of defenses which can lengthen the seepage path, minimize the uplift pressure at critical portions of the weir structure to make it safe against piping and uplift.

10.11.5 Drilling results at weir site

A borehole BH-1, has been drilled at left side slope to investigate the subsurface geological conditions. The location of the boreholes is presented (Vol-2, AFS-GE-316). No rock has been encountered in this borehole upto 90 m. The core recovery CR (%) and permeability test results are given in Table 10-2, and graphically presented in Figure 10-1. The permeability tests were conducted after every 3 m, in most of test head could not maintained due to cavities/ open works encounter in subsurface. The borehole has been stabilized with cement.

Table 10-2 core recovery CR (%) and permeability test results

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

It is noticed that head could not be maintained throughout the drilling of borehole. 100 % water loss has been observed. It indicates that slided mass is highly permeable with large cavities and open works required cementing for stabilization of bore holes during drilling.

10.11.6 Seepage Line of Defenses

If the Structure is to be placed on it, it requires treatment of strata with stabilized soil from 4 to 14 m from (El: 2412 to 2402 m.a.s.l). The stabilized portion is not needed in the stilling basin area. There is enough permeable layers present from (El: 2402 to 2396 m.a.s.l). Beneath is there is close to free draining.

To cater with the above problem following seepage line of defenses have been provided:

- Stabilized clayey soil
- Cement Slurry Cutoff/ Plastic Piles
- Clay Blanket to cover the upstream face of the Slide material

Trial analysis have been done on the above combinations and finally the cross section so selected for final analysis of all the parameters mentioned in 10.11.1 above. The final cross section so selected in shown in **Figure 2-1 (Volume 7, Appendices)** and in **Figure 10.4** below:

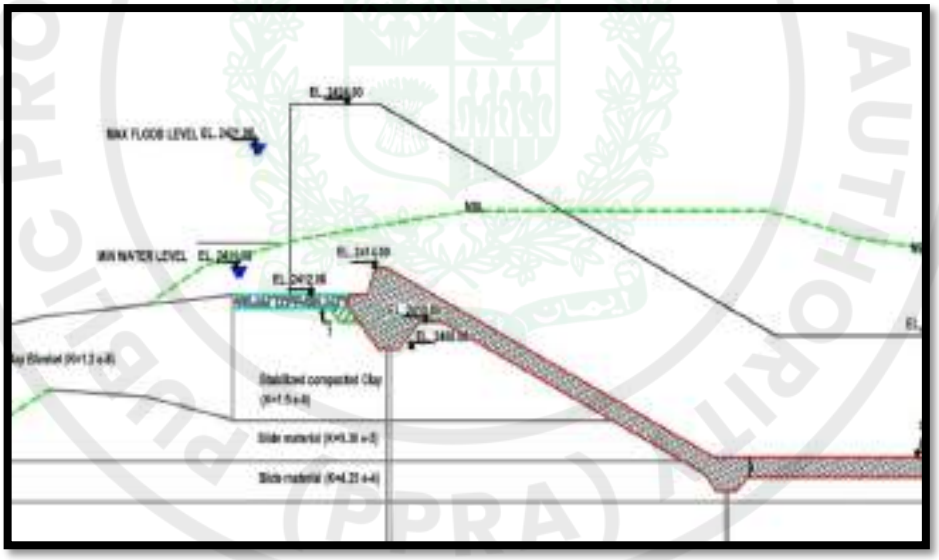

Figure 10-4: Selected weir cross section with all seepage line of Defenses

10.11.7 Selection of Stabilized Soil

The material for stabilized soil is taken from Power House Area and processed. The Soil classification done and processed soil is found to be silty clay material A-4 according to AASTHO after performance of sieve analysis, hydrometer analysis and Atterberg Limits. The results of the Sieve Analysis and Hydrometer are shown in **Figure 10.5** below:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

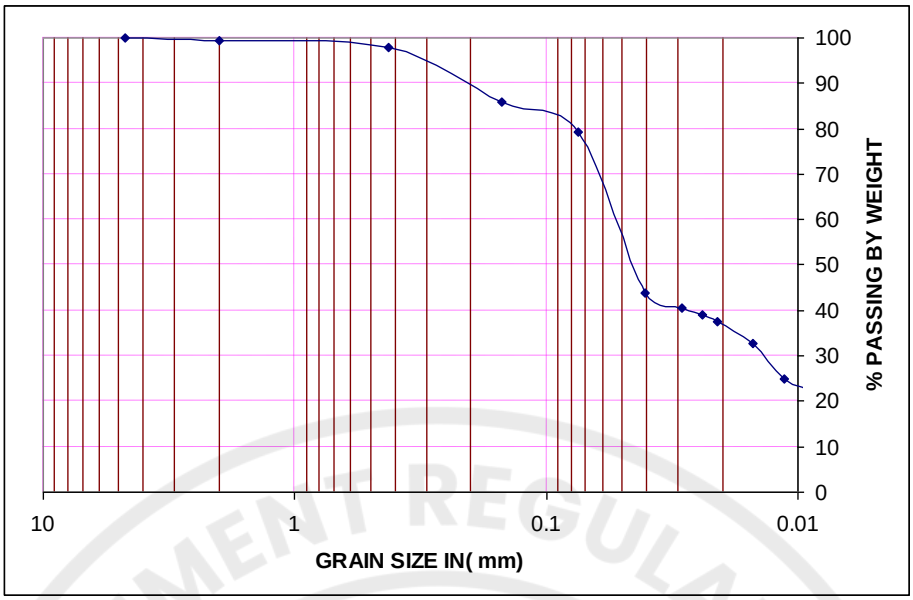

Figure 10-5: Sieve Analysis of Soil used for Stabilization

After classifying the soil, different samples were made with 0%, 2%, 4%, 6%, 8% and 10% of cement (3 samples for each %age). These samples were tested immediately and after 7, 14 days of casting by unconfined compression test. The results of the unconfined compression test are shown in **Figure 10.6 to 10.8** hereafter.

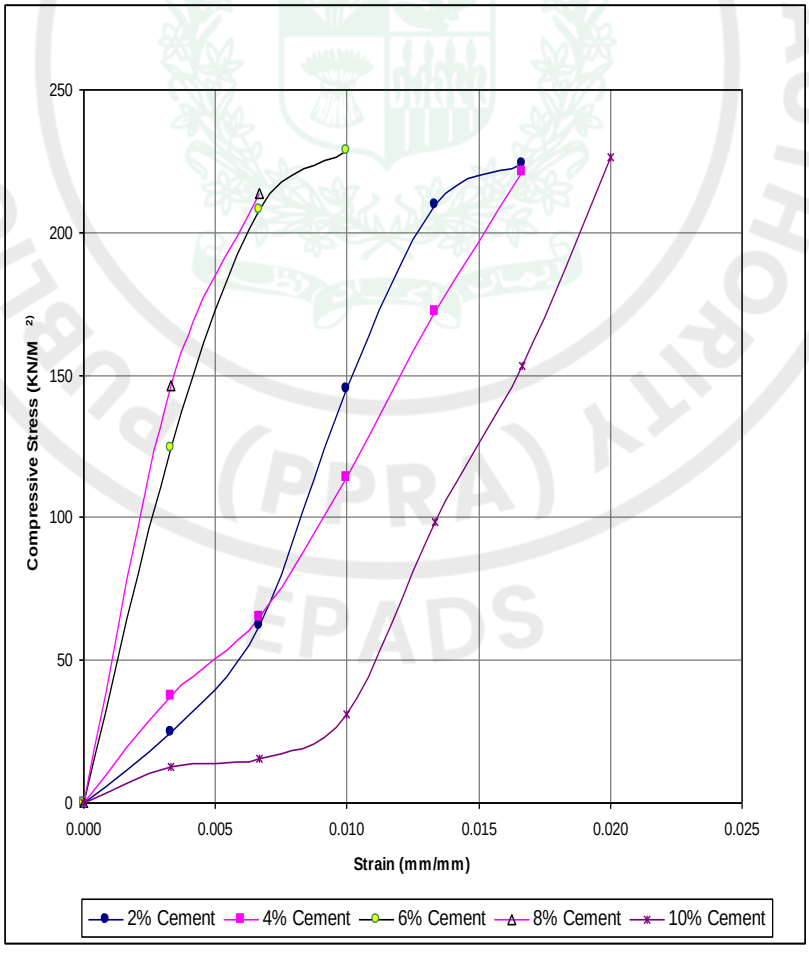

Figure 10-6: Stress Strain Results of the unconfined compression test immediately after mixing cement

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

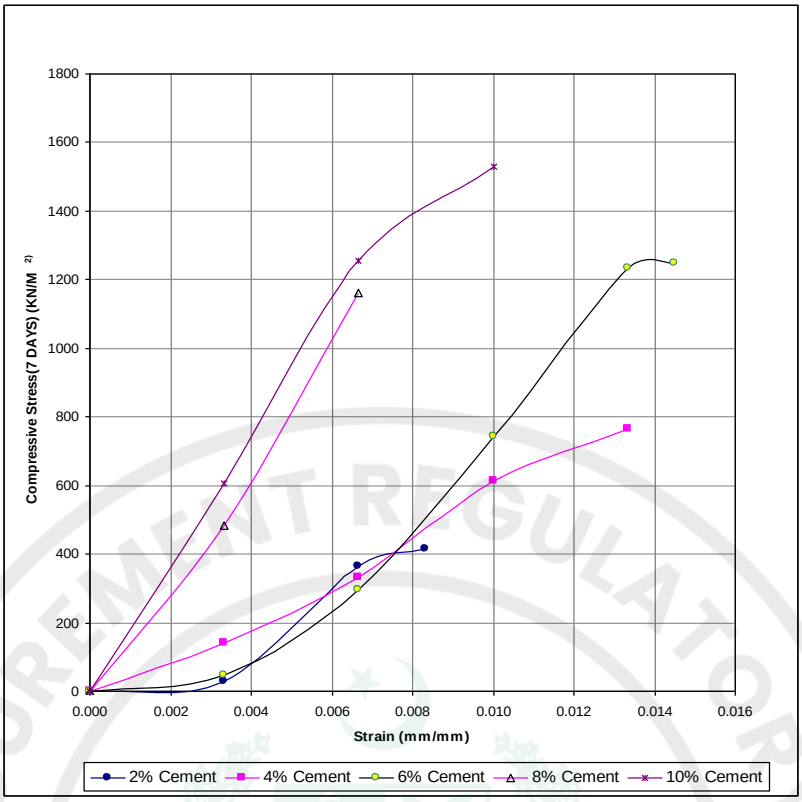

Figure 10-7: Stress Strain Results of the unconfined compression test immediately after 7 days of mixing cement

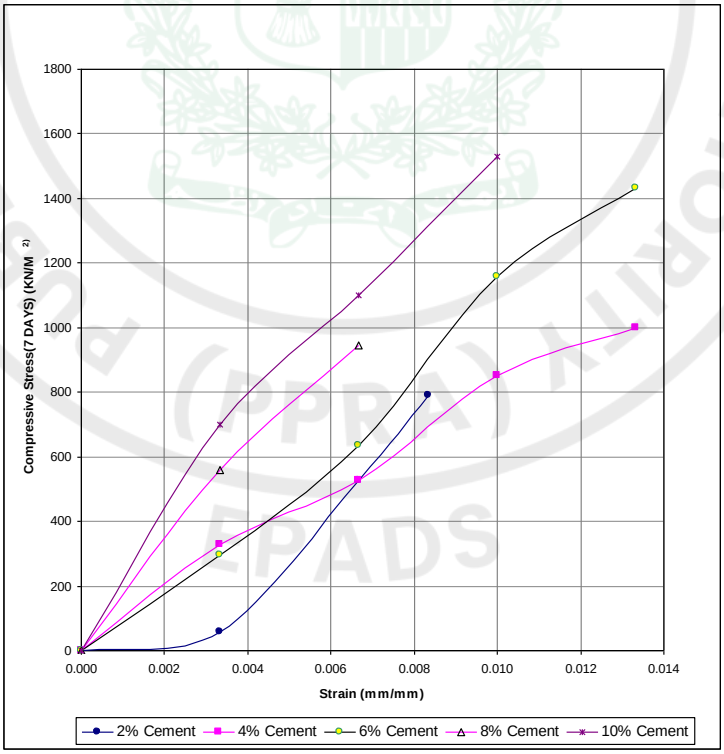

Figure 10-8: Stress Strain Results of the unconfined compression test immediately after 14 days of mixing cement

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The Summary of the Stress Strain Results and reduction of Plasticity index are shown in **Table 10.3** below:

Table 10-3 Borehole Drilling Summary at Weir Site

Samples		0%	2%	4%	6%	8%	10%
"C" in kPa	0 days	82.79	112.035	110.5	114.34	107	113.185
	7 days	82.79	207.395	381.9	642.47	734	750+
	14 days	82.79	394.67	500.48	716	749.39	750+
P.I %		7.22	6.75	5.95	4.73	4.17	3.42
Reduction in P.I		-	6.50%	17.60%	34.48	42.20%	52.63%

For economical consideration the soil with 2 % cement stabilization has been selected for the analysis and placement below the weir section. Almost 4 times the stabilization is achieved in terms of cohesion while the Plasticity index is already not in danger zone.

10.11.8 Material Description and Input Parameters

The permeability for the dyke foundation is taken from the permeability tests performed during borehole drilling and the for stabilized soil it's determined in laboratory.

For Stabilized soil beneath weir

1.5×10^{-8} m/sec

For slide material (El: 2402 to 2399m.a.s.l):

9.38×10^{-5} m/sec

For slide material (El: 2402 to 2399m.a.s.l):

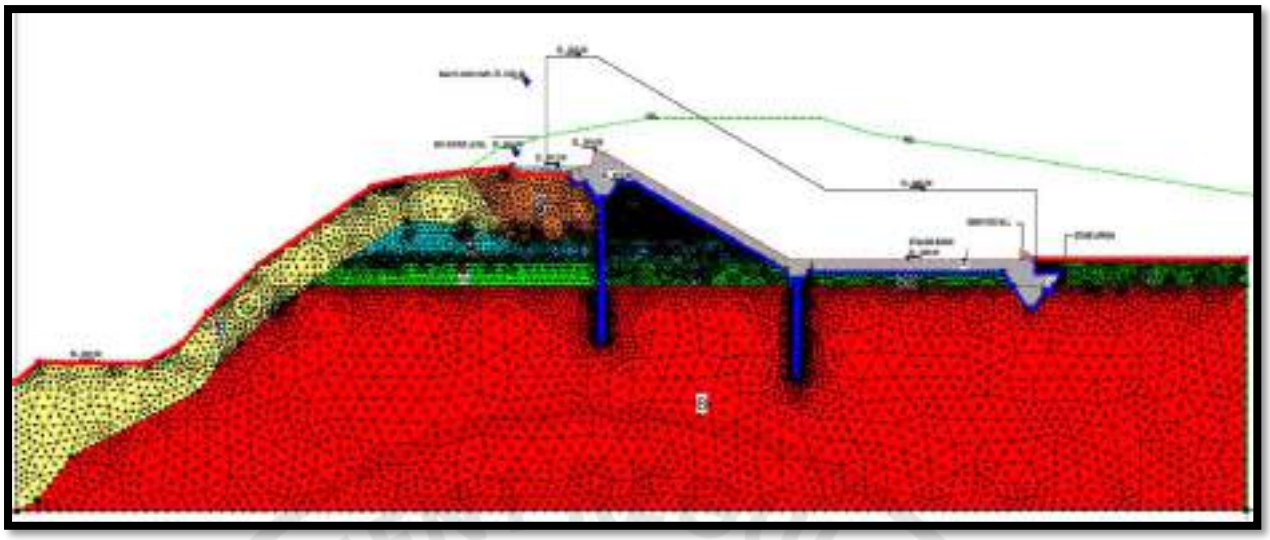
4.25×10^{-4} m/sec

10.11.9 Geostudio (SEEP/W Analysis)

The Analysis is performed in Seep/w, a sub program of Geostudio.

The Finite element model has been prepared with Steady Seepage conditions by inputting the proper structural sizes and material properties. Water head and flux (total and unit) boundary conditions have been applied at appropriate edges within the FEM model alongwith potential seepage review face on both of the right and left embankments of channelized section. The FEM Model prepared is shown in **Figure 2-13 (Volume 7, Appendices)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026



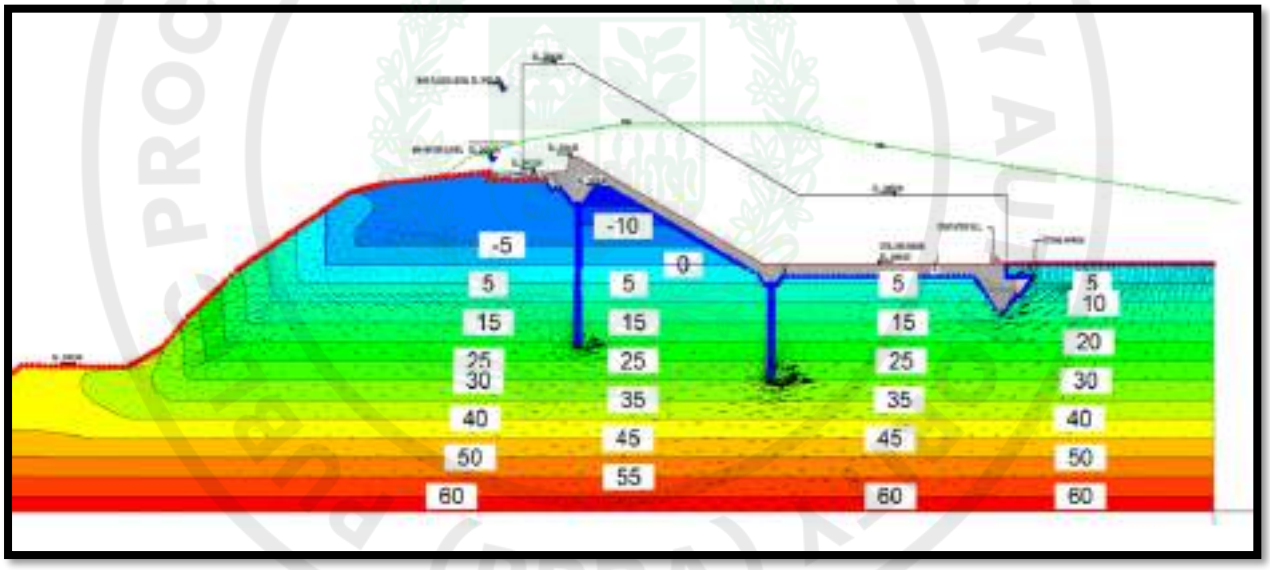


Figure 10-9 Weir Structure at Minimum Pond Level (El : 2414m.a.s.l)

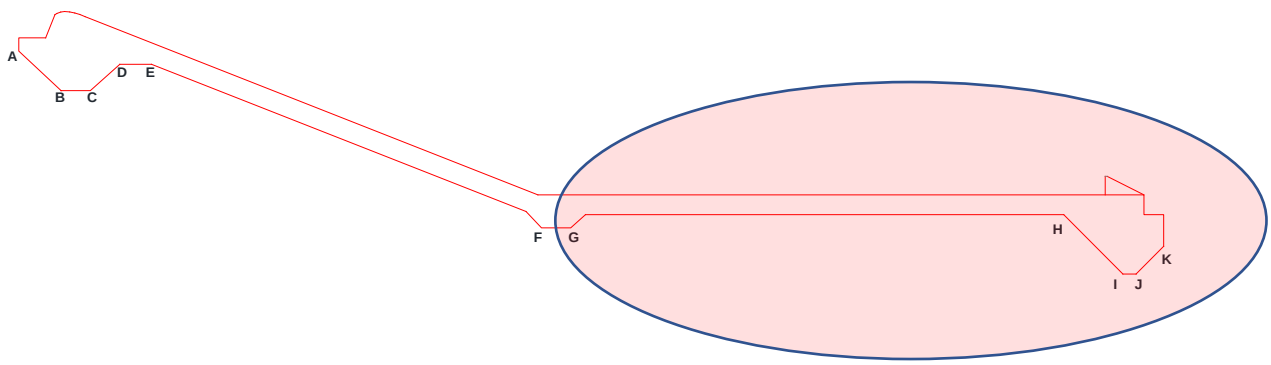
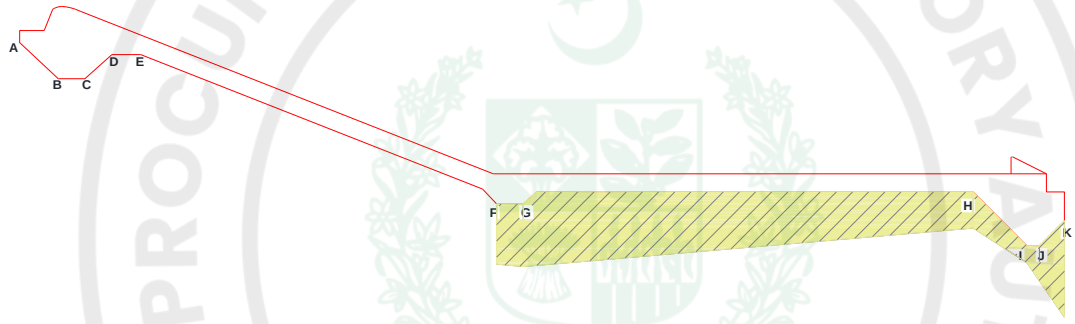


Safety against Uplift:

The Pressure head Profile is shown from **Figure 2-13 (Volume 7, Appendices)**.

It is quite evident from the Pressure Head Profile and visualization of phreatic surface within the foundation, only the downstream portion is critical against any uplift to check.



Pressure heads have been found at nine Nos. already provided Pressure points beneath the Barrage Structure.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Pt #	Press Head (m)
F	5
G	5.2
H	3
I	1.4
J	1.6
K	8

Based on the Pressure Heads obtained from the SEEP/W, pressure head envelop has been plotted beneath the structure as follows:

The Hydraulic Force per unit length of the weir is calculated by the following equation:

- U= Unit Weight of water x Area of the Pressure head Diagram
- Area of pressure diagram between A & G= 201.3 m^2
- Unit weight of water = 9.81 KN/m^3
- U= (Total Hydraulic Force per Unit length) = 201.3 x 9.81= 1974.753 KN/m
- W=Weight of the Structure per unit length is calculated as = 2436 KN/m
- F.O.S against uplift= W/U= 1.24 (STRUCTURE IS SAFE AGAINST UPLIFT at WL EL: 2414 m.a.s.l)

Safety against Piping:

According to Lane's weighted creep Theory the safety against Piping is ensured if:

$$\boldsymbol{L_{req} > CH}$$

Where;

L_{req} = Required Seepage Length

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

$C =$ Coefficient taking into account the soil characteristics

$H =$ Maximum Head

According to lanes;

L available = L (vertical)+ 1/3*L(horizontal)

Where;

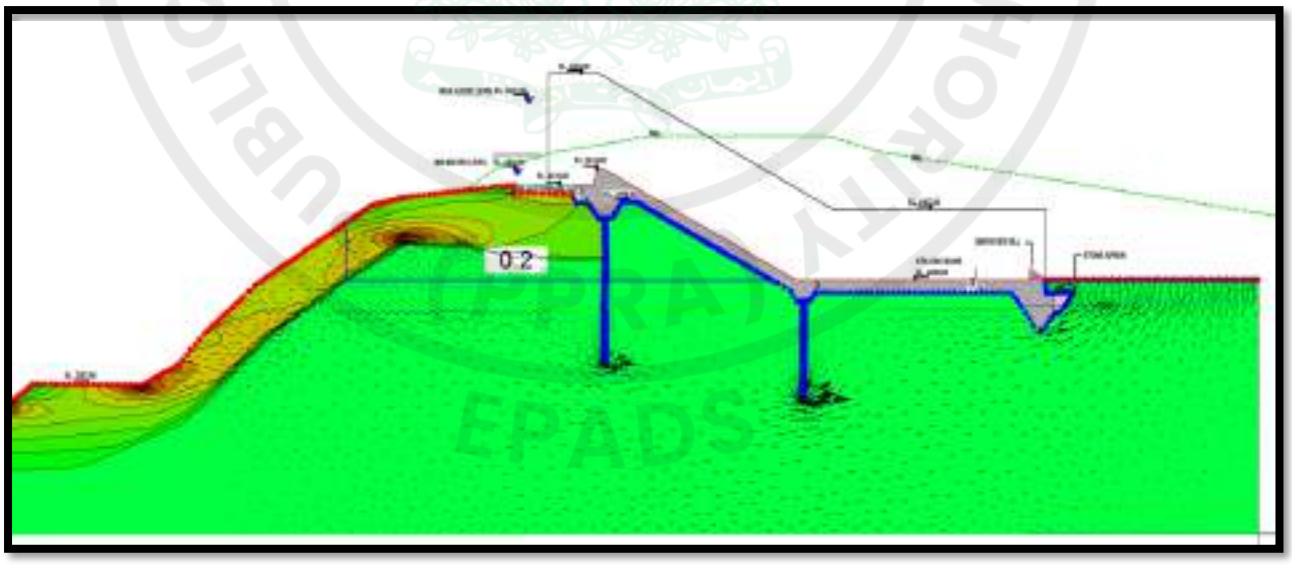
L available = Available Seepage length under the foundation

L (vertical) = Total vertical seepage length

L (horizontal) = Total Horizontal Seepage length

For Chashma Hydropower Project:

L available=79.8 + 1/3 (72.02) = 103.8 m



$L_{req} = CH$ = 14 X 3 = 42 m

L available >L_{req}, i.e. 103.8> 42

Hence, the weir structure is safe against piping forces.

Safety against piping d/s of weir through exit gradient criteria.

The Exit gradient profile computed from Geostudio SEEP/W Analysis is shown in **Figure 2-14 (Volume 7, Appendices)**

Exit gradient from Seep/W analysis= 0.2

Critical Hydraulic gradient= (Gs-1)/(1+e)

Where Gs= specific gravity

e= void ratio

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Critical Hydraulic gradient= (2.66-1)/(1+0.95)=0.85

Factor of Safety against piping =i (critical)/ i exit=0.85/0.2= 4.25 > 1, hence the weir structure is safe against piping.

10.11.9.1 Weir Structure at Maximum Pond Level (El :2424m)

Safety against Piping:

According to Lane's weighted creep Theory the safety against Piping is ensured if:

$$\boldsymbol{L_{req} > CH}$$

Where;

$L_{req} =$ Required Seepage Length

$\mathrm{C} =$ Coefficient taking into account the soil characteristics

$\mathrm{H} =$ Maximum Head

According to lanes;

L available = L (vertical)+ 1/3*L(horizontal)

Where;

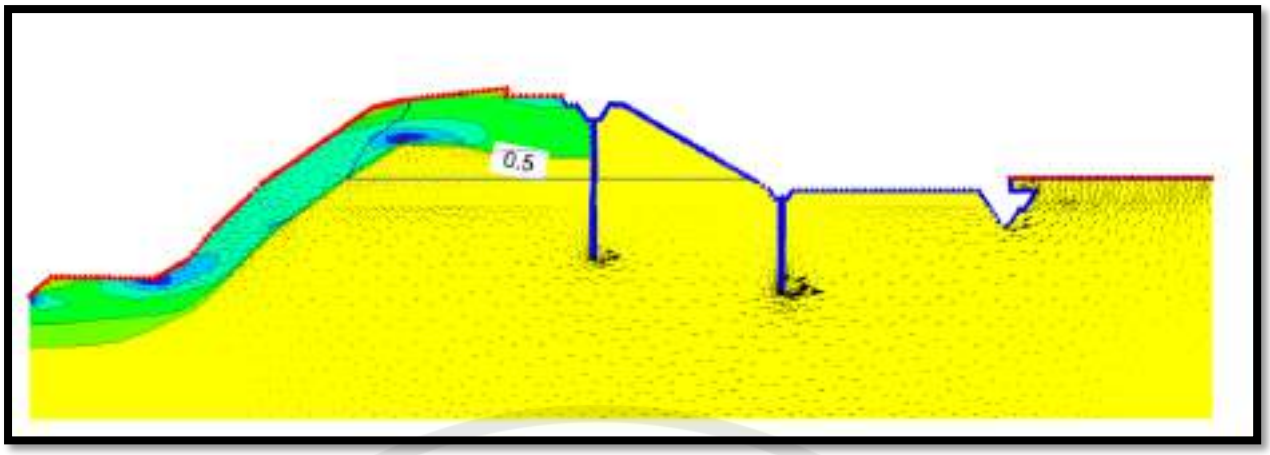
L available = Available Seepage length under the foundation

L (vertical) = Total vertical seepage length

L (horizontal) = Total Horizontal Seepage length

L available=79.8 + 1/3 (72.02) = 103.8 m

$\mathrm{L_{req}} = \mathrm{CH}$ = 24 X 3 = 72 m



L available >$\mathrm{L_{req}}$, i.e. 103.8> 72

Hence, the weir structure is safe against piping forces.

Safety against piping d/s of weir through exit gradient criteria.

The Exit gradient profile computed from Geostudio SEEP/W Analysis is shown in **Figure 2-15 (Volume 7, Appendices)**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Exit gradient from Seep/W analysis= 0.5

Critical Hydraulic gradient= (Gs-1)/(1+e)

Where

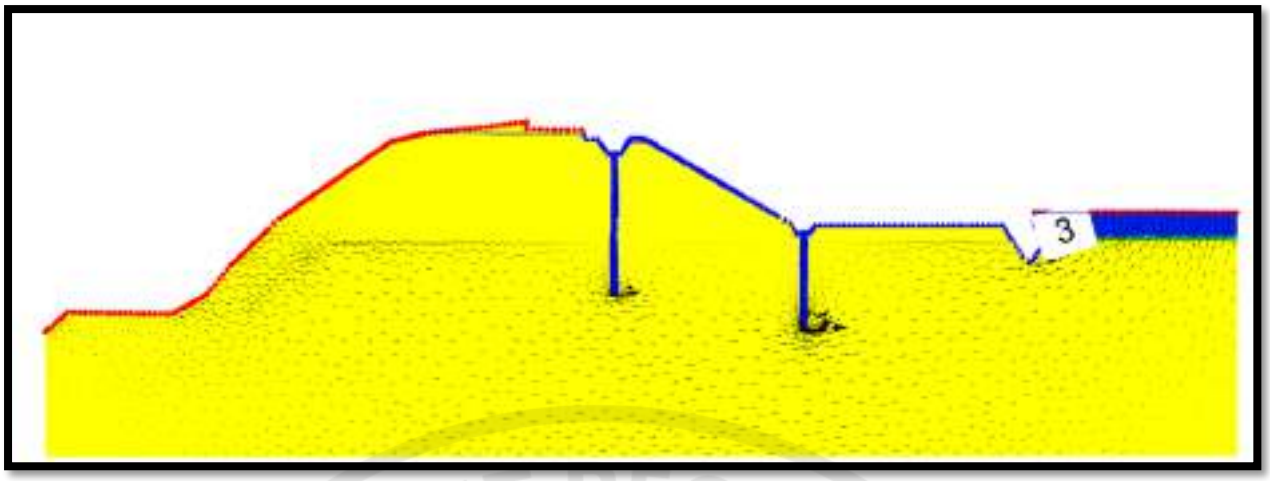
Gs= specific gravity

e= void ratio

Critical Hydraulic gradient= (2.66-1)/(1+0.95)=0.85

Factor of Safety against piping =i (critical)/ i exit=0.85/0.5= 1.7> 1, hence the weir structure is safe against piping.

Due to proper seepage line of defences the phi and equipotential lines for max pond level are well below the weir foundation and follows almost same pattern at stilling basin area. The safety against piping was critical which has been checked above.



The clay blanket alongwith cement slurry cutoff and stabilized soil proved to be best in stabilizing the weir structure over the slided material.

For comparison the safety against piping has been checked for weir structure without clay blanket upstream, just to show that its presence upstream is so critical. The structure has been failed as shown below:

Safety against piping d/s of weir through exit gradient criteria at highest pond level 2424 m.a.s.l without clay blanket.

The Exit gradient profile computed from Geostudio SEEP/W Analysis is shown in **Figure 2-16 (Volume 7, Appendices)**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Exit gradient from Seep/W analysis= 3

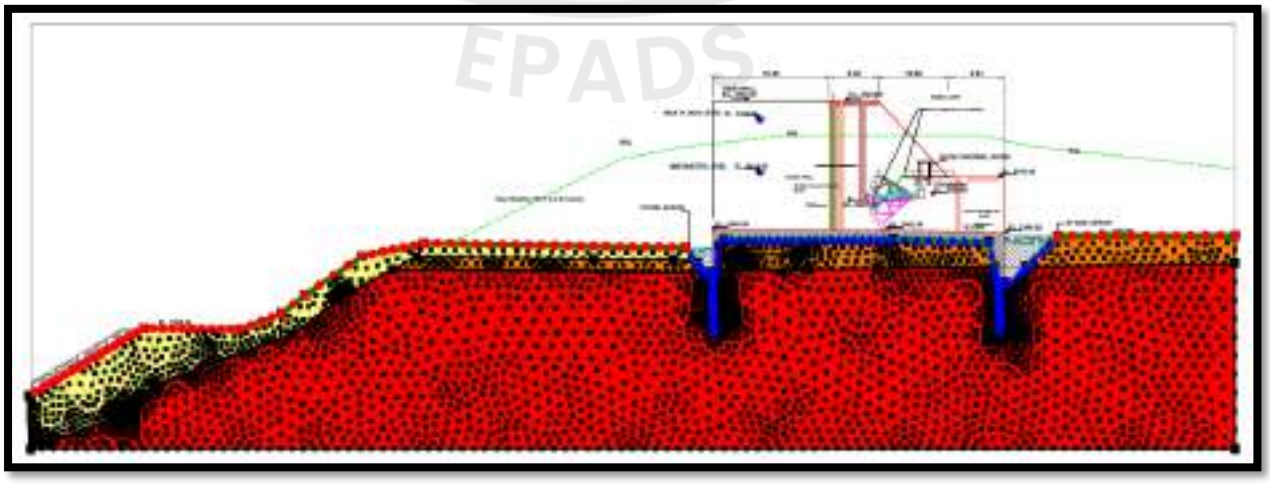
Critical Hydraulic gradient= (Gs-1)/(1+e)

Where

Gs= specific gravity

e= void ratio

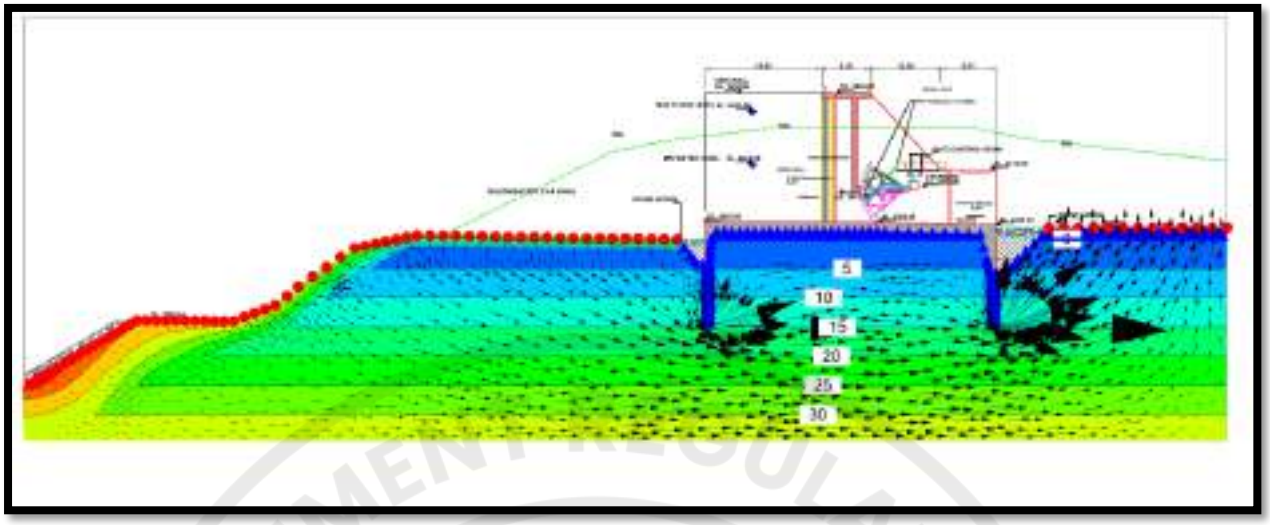
Critical Hydraulic gradient= (2.66-1)/(1+0.95)=0.85



Factor of Safety against piping =i (critical)/ i exit=0.85/3= 0.28> 1, hence the weir structure is not safe against piping when clay blanket is removed.

Under sluice Structure at Maximum Pond Level (El: 2424m.a.s.l)

Safety against Uplift:



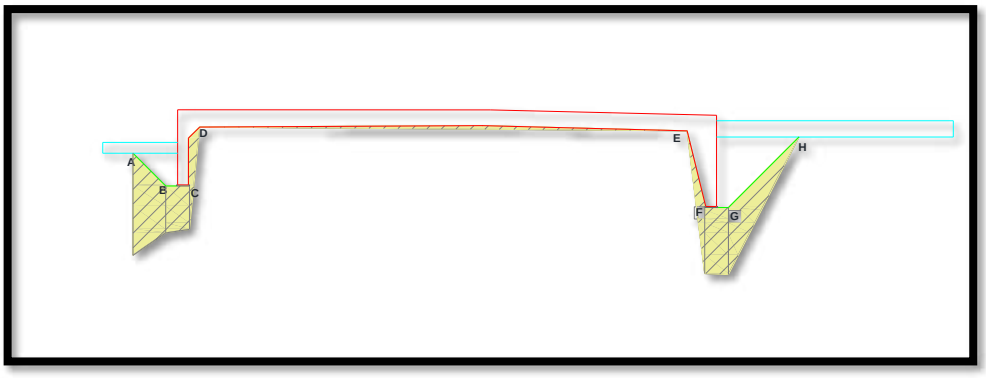
The Cross section finalized for analysis is shown in **Figure 2-17 (Volume 7, Appendices)**. Seepage line of defenses are upstream clay blanket and pile cutoffs.

The Finite Element model of under sluice section is shown in **Figure 2-18 (Volume 7, Appendices)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The Pressure head Profile is shown in **Figure 2-18 (Volume 7, Appendices)**.

It is quite evident from the Pressure Head Profile and visualization of phreatic surface within the foundation, only the downstream portion is critical against any uplift to check.



Pressure heads have been found at nine Nos. already provided Pressure points beneath the Barrage Structure.

Pt #	Press Head (m)

Based on the pressure heads obtained from the SEEP/W, pressure head envelop has been plotted beneath the structure as follows:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The Hydraulic Force per unit length of the weir is calculated by the following equation:

- U= Unit Weight of water x Area of the Pressure head Diagram
- Area of pressure diagram between A & G 82.51 m^2
- Unit weight of water 9.81 KN/m^3
- U= (Total Hydraulic Force per Unit length) 82.51 x 9.81 = 809.42 KN/m
- W=Weight of the Structure per unit length is calculated as 3147 KN/m
- F.O.S against uplift W/U 3.88 **(STRUCTURE IS SAFE AGAINST UPLIFT at WL EL: 2424 m.a.s.l)**

Safety against Piping:

According to Lane's weighted creep Theory the safety against Piping is ensured if:

$$L_{req} > CH$$

Where;

L_{req} = Required Seepage Length

C = Coefficient taking into account the soil characteristics

H = Maximum Head

According to lanes;

L available = L (vertical)+ 1/3*L(horizontal)

Where;

L available = Available Seepage length under the foundation

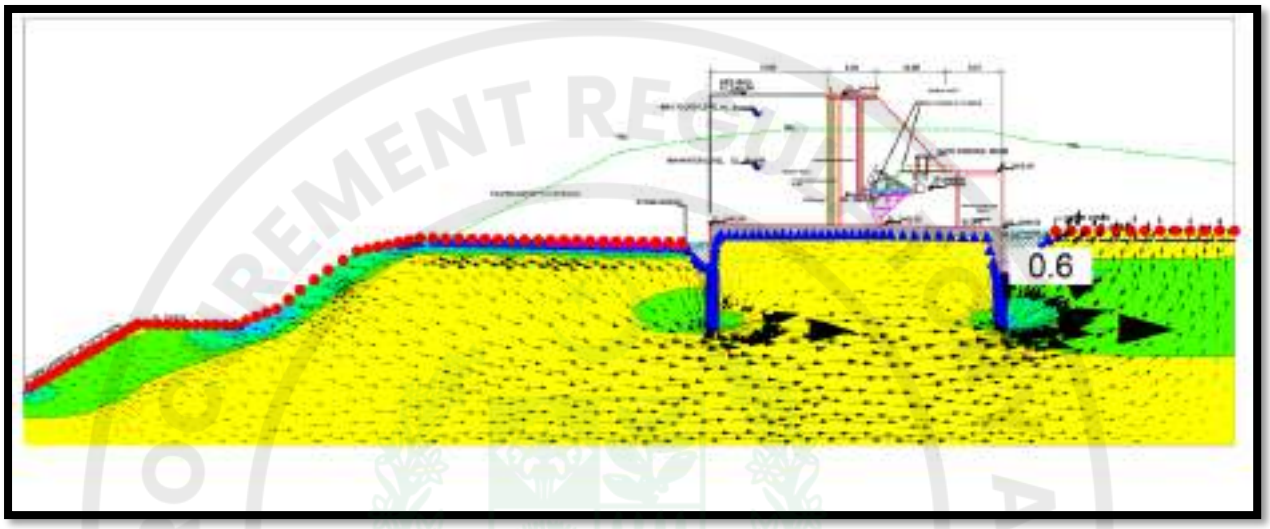
L (vertical) = Total vertical seepage length

L (horizontal) = Total Horizontal Seepage length

:

L available=64.648 + 1/3 (49.38) = 81 m

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026



$L_{req} = CH$ = 24 X 3 = 72 m

L available >L_{req}, i.e. 81> 72

Hence, the weir structure is safe against piping forces.

Safety against piping d/s of barrage through exit gradient criteria.

The Exit gradient profile computed from Geostudio SEEP/W Analysis is shown in **Figure 2-20 (Volume 7, Appendices).**

Exit gradient from Seep/W analysis 0.6

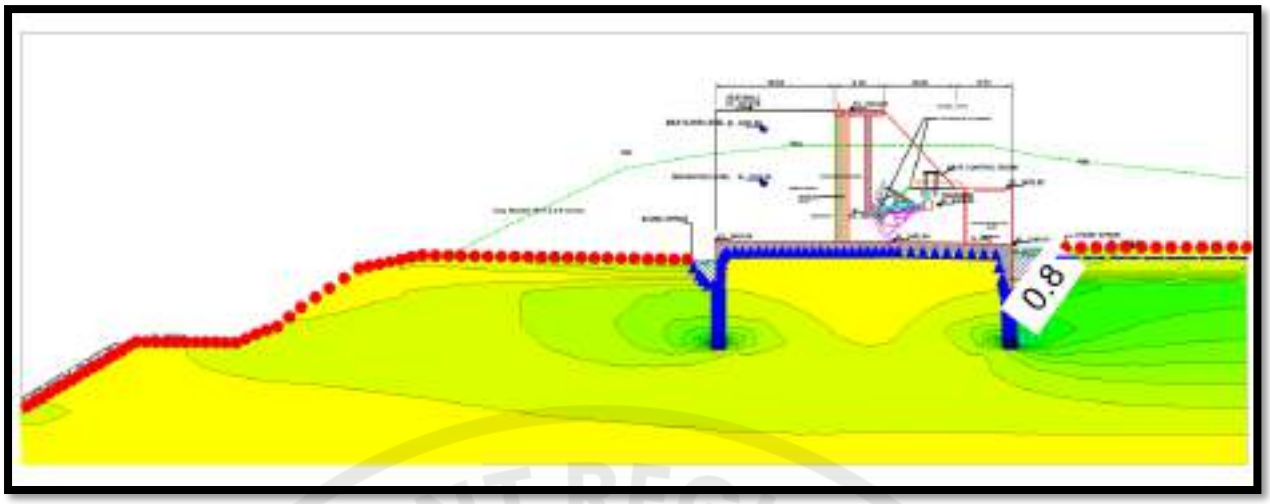
Critical Hydraulic gradient (Gs-1)/(1+e)

Where Gs= specific gravity

e= void ratio

Critical Hydraulic gradient (2.66-1)/(1+0.95)=0.85

Factor of Safety against piping =i (critical)/ i exit=0.85/0.6= 1.41> 1, hence the weir structure is safe against piping.



10.11.9.2 Overflow Weir Structure at Max Pond Level without Blanket (El: 2424 m.a.s.l)

For comparison the safety against piping has been checked for overflow weir/ungated spillway structure without clay blanket upstream, just to show that its presence upstream is so critical. The structure has been failed details are given below:

Safety against piping d/s of sediment flushing channel /under sluice through exit gradient criteria at highest pond level 2424 m.a.s.l without clay blanket.

The Exit gradient profile computed from Geostudio SEEP/W Analysis is shown in **Figure 2-21 (Volume 7, Appendices)**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Exit gradient from Seep/W analysis= 0.8

Critical Hydraulic gradient= (Gs-1)/(1+e)

Where

Gs= specific gravity

e= void ratio

Critical Hydraulic gradient= (2.66-1)/(1+0.95)=0.85

Factor of Safety against piping =i (critical)/ i exit=0.85/0.8= say equal to 1, hence the sediment flushing channel/ undersluice structure is not safe against piping when clay blanket is removed.

10.12 MONITORING AND SURVILANCE OF SLOPES

Slope indicators are proposed on right side slope benching starting from overflow weir site at chainage 100+00 towards downstream @ 100m. They are really necessary to use to measure relative and absolute (total) horizontal (lateral) movement, and/or variation in inclination, with respect to a vertical or inclined reference axis.

Lateral movements in structures are measured by use of borehole slope indicators (Inclinometers). The slope indicator casing may be installed during construction of the dam, or, after in the event that excessive displacement is observed.

The instrumentation basically will be comprising of a specially designed access tube (duct), with incorporated guide tracks, which is embedded in the respective structure, embankment or foundation, aligned along the selected measurement reference axis. The access tubing is of segmental construction with telescoping joints to accommodate extension/compression movements.

The tilt of the sensor will be measured and recorded by servo-accelerometer located within the probe. Where two accelerometer are used they can sense the inclination of the tube in two directions at right angles to each other.

Portable electronic probes, with attached calibrated measurement/control cables, are provided for insertion and traversing along the access tube(s) for reading purposes. The probe readings

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

are taken with special electronic readout units capable of storing the readings for subsequent direct downloading to a computer for purposes of analysis. Analysis of the readings is carried out by special computer software provided as part of the instrument package.

In the case of the inclinometer probes, readings of the inclination of the access tube at selected points are taken in two orthogonal directions (i.e. at 90^{o} to each other) over the fixed gauge length of the probe, and by taking a series of continuous readings a profile of the deflected shape of the access tube corresponding to the deflection within the structure, embankment, or foundation can be obtained.

Provision is made in the supplied computer software for the graphical plotting of the deflected shapes and the determination of both absolute (total) and relative (incremental) displacements with time.

The accuracy of measurement is 3 mm.

Inclinometer consists of;

- Aluminum access tube (in small lengths)
- Biaxial probe
- Inclinometer data logger

The cross section details of slope indicator are presented in **Figure 10.9 & 10.10** below:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

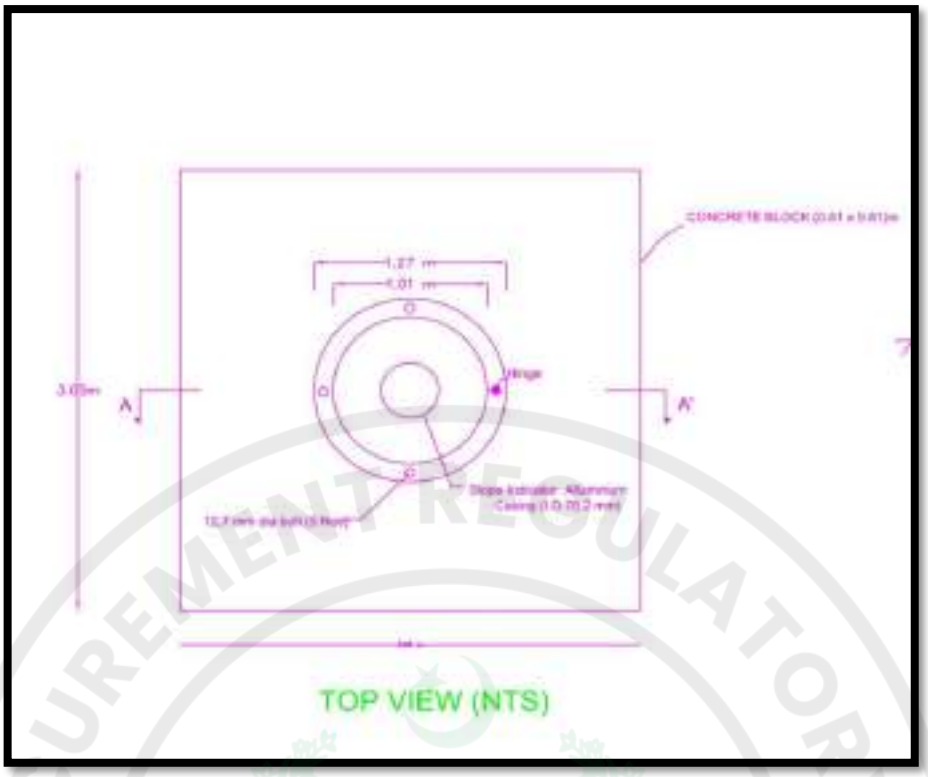


Figure 10-10: Cross Section details of Slope Indicator (Top view)

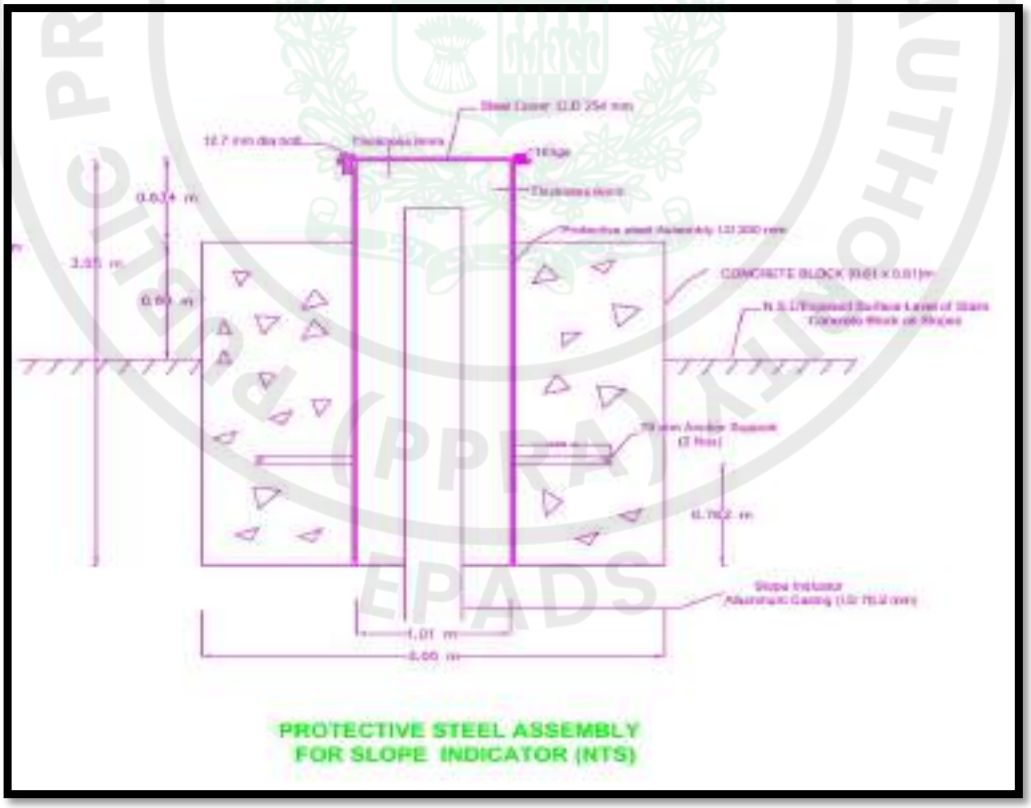

Figure 10-11: Cross Section details of Slope Indicator (cross section)

The depth of the slope indicator will be upto bottom of the final stepping/ bench and will start from one above the middle bench of the benched slope.

11 HYDRO MECHANICAL EQUIPMENT

11.1 INTRODUCTION

11.1.1 BACKGROUND

Energy is the indispensable force that drives all economic activity the greater the energy consumption, the more the economic activity, resulting in the emergence of growth. A steady growth in the economy is a prerequisite for any nation desirous of becoming a developed country. If Pakistan adequately utilizes its energy potential to meet growing demand, it will be better poised to achieve high levels of economic growth.

Hydropower is a clean, domestic, and renewable source of energy. It provides inexpensive electricity and produces no pollution. Unlike fossil fuels, hydropower does not destroy water during the production of electricity. Hydropower is the only renewable source of energy that can replace fossil fuels' electricity production while satisfying growing energy needs. According to some estimates, Pakistan is endowed with a potential of about 40,000 MW but only 11.0% of it is presently being utilized for generation of electricity leaving the remaining untapped.

Considering the electric industry that exists today, hydropower has a distinct advantage over fossil fueled generator plants: it is clean, green and renewable. Hydropower does not contribute to local air pollution. Other energy generators are an important source of air, water, and soil pollution and greenhouse gases, and provide fewer opportunities for economic spin-offs.

11.1.2 Location

Attabad is a town in the Gilgit-Baltistan region of northern Pakistan. It is located at 36°19'0N 74°48'0E with an altitude of 2559 meters (8398 feet) and is famous as home of the Attabad lake. The lake was formed when Attabad Village in Hunza Valley in Gilgit-Baltistan had a landslide, 14 kilometers (9 miles) upstream (east) of Karimabad that occurred on 4th January, 2010. Location for the Proposed Attabad Hunza Hydropower Project has been identified in the intermediate reach along Hunza River 29km upstream of Aliabad Village and 111km from Gilgit.

11.1.3 Parameters

To arrive at the optimum unit rating and parameters of the power plant detailed studies for the various possible alternates were carried out. From these studies it was concluded that installation of generating units of capacity 54 MW corresponding to 375 rpm synchronous speed would be the optimum solution. The key characteristics of the unit selected for Attabad Hydro Power Project, are given below.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Full Supply Level (FSL)	2414 m.a.s.l
Minimum Operating Level (MOL)	2412 m.a.s.l
Maximum Tail water Level	2307 m.a.s.l
Minimum Tail water Level	2302 m.a.s.l
Site Gross Head	112 m
Rated Net Head	106 m
Installed capacity	54 MW
No. of Generating Units	03
Units Rated Capacity	18 MW (Generator Output)
Turbine Rated Capacity	57 MW
Plant Overall Efficiency	90.28% (0.915(T)x0.98(G)x0.985(T_f))
Transformer Capacity	66 MVA (3 x 22)
Generator Voltage	11 kV
Power Factor	0.85
Powerhouse Cavern	45 m x 18 m x 22 m (L x W x H)
Transmission Voltage	132 KV

11.2 POWER HOUSE MECANICAL WORKS

11.2.1 General

This section provides general information and guidelines used for the feasibility design of the hydro-mechanical equipment for Attabad Hydro power project (AHPP). It also covers the characteristics of these equipment and various factors used to establish the size and configuration of such type of equipment. The key dimensions of turbine are also workout and given in this chapter.

11.2.2 Introduction

The mechanical equipment of Attabad Hydropower Project consists of the following main components:

- Vertical Shaft Francis Turbines
- Turbine governors
- Main Inlet Valves
- Powerhouse Main Crane
- Station Auxiliaries
- Cooling Water System

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Drainage and Dewatering System
- Compressed Air System
- Oil Handling System
- HVAC System
- Fire Fighting System
- Mechanical Workshop Equipment
- Elevator
- Potable Water Supply and Sanitation System

11.3 STANDARDS AND BASIC DESIGN CRITERIA

The mechanical equipment will be designed according to the well reputed international standards and codes like IEC, ISO, EN, ASTM, ASME, BSS, DIN, etc.

11.4 MAIN DESIGN PARAMETERS

11.4.1 Water Flow

Flow Duration Curve (FDC) for Attabad Lake HPP is plotted on the basis of almost 51 years (1966-2016). From FDC it us evident that design discharge of 60 m^3/s is available for almost 50% of the time. Therefore, design discharge of 60 m^3/s is justified for the generation of 54 MW power.

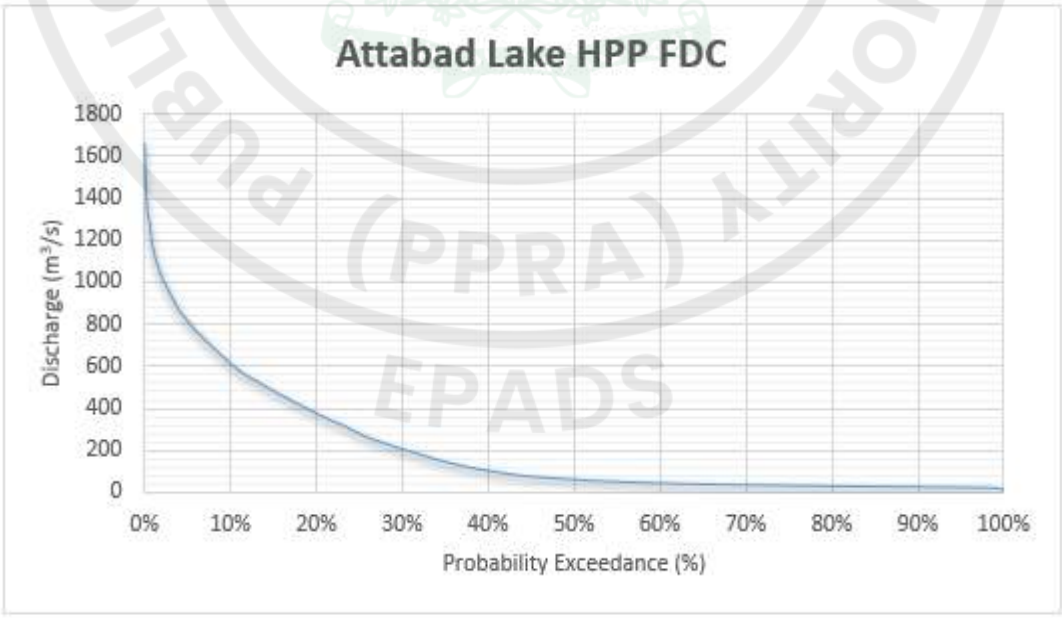

Figure 11-1 Attabad Lake Flow Duration Curve (FDC)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 11-1 Flow Duration Curve Results

Probability Exceedance (%)	Flow (m3/s)	Probability Exceedance (%)	Flow (m3/s)
10	613.4	60	44.3
20	376.6	70	36
30	205	80	30.3
40	103.3	90	26.2
50	61.3	99	20.5

11.4.2 Head Calculation

Head water Level

The Full Supply Level (FSL) of AHPP is 2414 m.a.s.l., while minimum Operation Level (MOL) is about 2412 m.a.s.l. depending upon the availability of flows.

Tail water Level

Since there is fluctuation of flow, thus tail water level will also be changing accordingly. Maximum tail water level has been recorded as 2307 m.a.s.l. and minimum tail water level is 2302 m.a.s.l.

11.4.3 Water Head

Gross head

On the basis of selected water levels calculated gross head will be:

Site Gross Head: 112 m

Rated net head

Considering the head variation, friction losses and turbine runner central line arrangement the selected rated net head for AHPP is as follows:

Maximum Net Head: 108 m

Rated Net Head: 106 m

Minimum Net Head: 100 m

11.4.4 Site Elevation

Site elevation of AHPP powerhouse is 2358 m

11.4.5 Water Temperature

Average water temperature at AHPP site is 10˚C

11.4.6 System frequency

System frequency of AHPP powerhouse equipment is 50 Hz

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

11.4.7 Plant Capacity

The Power has been carried out according to the following formula:

$$P = \rho \times g \times Q \times H \times \eta/1000$$

Where,

P= Power (MW)
ρ = Density of water = 1 (ton/m^3)
Q = Discharge (m^3/sec)
H = Available head (m)
g = Acceleration due to gravity (9.81 m/sec^2)
η = overall Efficiency coefficient (%)

On the bases of selected rated discharge of 60 m^3/sec and rated net head of 106 m and overall efficiency of turbine, generator & transformer is around 0.90. The installed capacity of power house comes out to be 54 MW.

11.5 POWERHOUSE MECHANICAL EQUIPMENT

The powerhouse will be equipped with three Vertical Shaft Francis turbines. The total plant out capacity of AHPP powerhouse is 54 MW. The turbine shall be capable to operate within a wide range of head and discharge at maximum attributable efficiency.

No. of Units = 03 (Vertical Francis)

Plant Discharge, Q_{Total} = 60 m^3/s

Rated Net Head, H_n =106 m

Plant Capacity, P_{Total} = 54 MW

Followings are the main powerhouse mechanical equipment.

- Turbines
- Governors
- Cooling and Service Water Systems
- Dewatering and Drainage Systems
- Potable water system
- Sewage and water treatment
- Compressed air Systems
- Oil handling system

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Heating Ventilation & Air-conditioning System
- Fire protection system
- Powerhouse Crane
- Powerhouse elevator
- Workshop equipment etc.

11.6 TURBINES

In the power house, three (03) turbine-generating units, each consisting of a Francis turbine and a synchronous generator rigidly coupled by a vertical shaft. Each turbine will be equipped with a main inlet valve of butterfly type at the inlet of the manifold. On the downstream side of each turbine, draft tube gates can be set to isolate the turbine pit from the tailrace channel.

At the power intake (in Attabad Lake), fixed wheel gate will be installed, which will act as emergency gate.

The size of powerhouse totally depends upon type of turbine and number of units. Discharge and net head basic is the key parameter and basic criteria for selecting the type of hydel turbine. Other factor such as gates, stop logs, trash racks, dewatering and drainage pits, loading and service bay are also important.

Since, the layout and dimensions of a powerhouse are mainly influenced by the selected type of turbine, particularly by arrangement of turbine axis either in horizontal or in vertical direction and discussed as follows:

11.6.1 Turbine Selection Criteria

In case of AHPP with gross head of 112 m, rated net head of 106 m and rated discharge of 60 m^3/sec, figure 2.2 & 2.3 refer Francis turbines to be the most suitable ones.

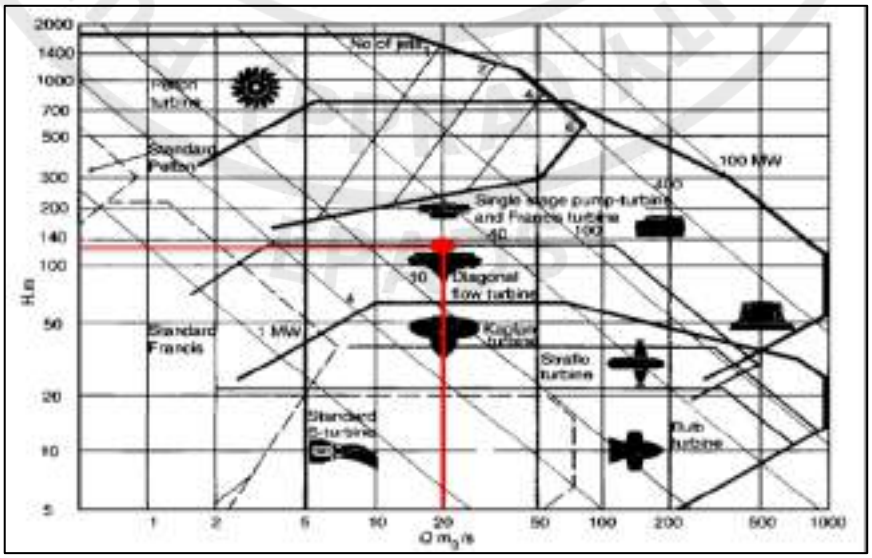

Figure 11-2 Generalized Turbine Operation Limits

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

(Courtesy Sulzer Hydro Ltd., Zurich)

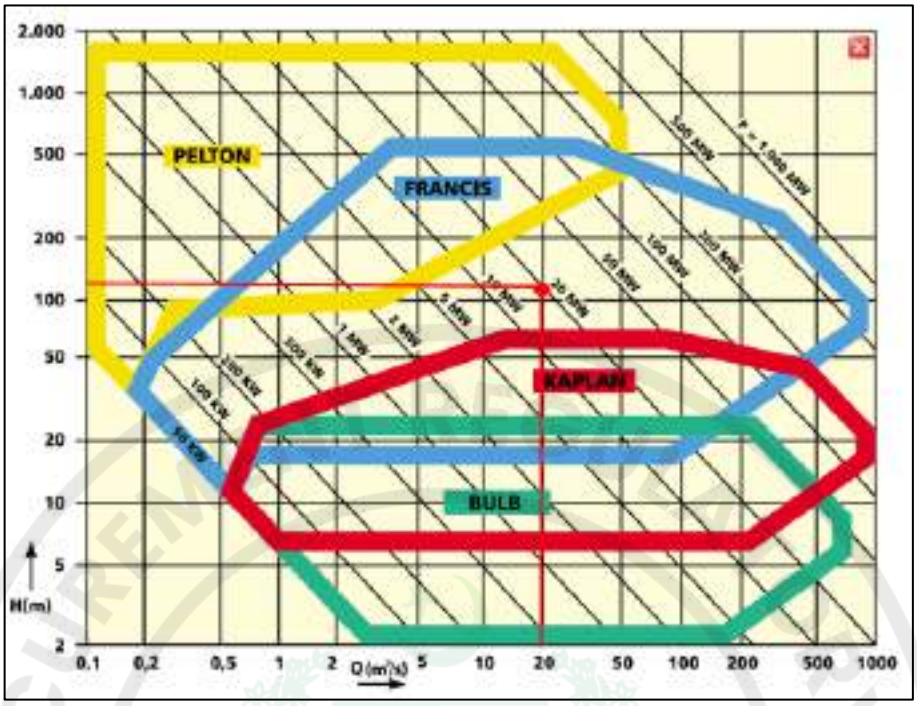

Figure 11-3 Turbine Operating Regimes

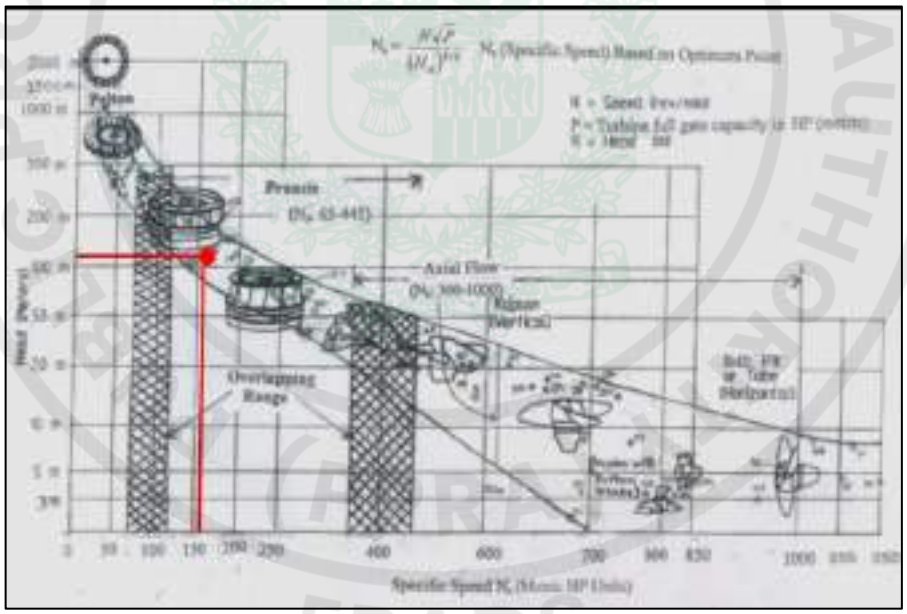

Figure 11-4 N_s Versus Head:

This figure shows the various turbine type as a function of specific speed (Ns) and head. This figure should be used a guideline, as there is overlap between the various turbine types with respect to their operating ranges (Based on ASME–Guide to Hydropower Mechanical Design Book)

Following standards and monographs are good guides for selection of hydraulic turbines.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- IS 12837 – 1989 – Hydraulic Turbines for Medium and Large Power Houses – Guidelines for Selection.

- IS 12800 (Part 3) 1991 – Guide lines for selection of hydraulic turbines, preliminary dimensioning and Layout of surface Hydro-Part 3 Small Mini and Micro Hydroelectric Power Houses.

Vertical Francis type turbine is best and appropriator solution for the rated discharge of 20 m^3/sec and rated net head of 106 m.

11.6.2 Specific Speed

The term specific speed used in classifying types of turbines and characteristics of turbines within types is generally the basis of selection procedure. This term is specified as the speed in revolution per minute at which the given turbine would rotate, if reduced homologically in size, so that it would develop one metric horse power at full gate opening under one-meter head. Low specific speeds are associated with high heads and high specific speeds are associated with low heads. Moreover, there is a wide range of specific speeds which may be suitable for a given head.

Flow based metric system for specific speed (N_q) is given by equation below.

$$\mathbf{N_q = \frac{NT^{0.5}}{H^{1.25}}}$$

Where,

N_q = Specific Speed

N = Speed in rpm

T = Turbine Power

H = Net Head in meters

$$N_q = \frac{375 * 19000^{0.5}}{106^{1.25}}$$

$$\mathbf{N_q = 152.0}$$

Specific speed (metric HP units) range of different types of turbines is as follows:

Fixed blade propeller turbines - 300 – 1000

Adjustable blade Kaplan turbines - 300 – 1000

Francis turbines - 65 – 445

Impulse turbines –

- Pelton Turbine per jet 16-20 per jet for multiple jets the power is proportionally increased.

- Cross flow turbine 12-80

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Specific speed is calculated to be 152.0 which lies in range of Francis turbine (65 – 445). Hence, vertical Francis turbine is best suitable for the specific speed of 152.0.

11.6.3 Number of units

Normally, it is most cost effective to have a minimum number of units at a given installation; however multiple units may be necessary due to various reasons. Thus for selecting number of units following factors should be considered.

- Efficient water use
- Getting Max energy
- Space limitation for civil structure
- Transportation Problems
- Maintenance View point
- Cost effectiveness

Table 11-2 Power Output with Different no. of Units for Attabad HPP

Number of Units		4	3	2
Unit Discharge	m^3/sec	15	20	30
Rated Turbine capacity	MW	14	19	29
Over all Plant Capacity	MW	53	54	55
Efficiency at rated discharge	%	90.0	90.0	90.0
Turbine Speed	rpm	429	375	333.3
Runner outer diameter	m	1.457	1.676	1.988
Crane capacity	Ton	60	80	100

11.6.4 Efficient Water Use

Efficient use of available water and getting maximum energy from hydropower station is necessary to maximize the profitability.

Selection of number of units plays a bridge role to achieve this target. On the feasibility stage, two units of same capacity and one with less capacity are considered.

One major factor for evaluation of number of units is how the power station will anticipate in operation. Particularly for AHPP, with 03 units operational reliability and given optimum annual energy. This operational advantage will also contribute in the annual energy produced by the project.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

11.6.5 Space Limitation for Civil Structure

Space limitation for geologic characteristic may dictate larger or smaller units. In case of AHPP, turbine capacity is 19 MW. From the Civil structure & Geologic viewpoint, no major hindrance found in power house side.

11.6.6 Maintenance View Point

More the number of units higher the operation and maintenance (O&M) cost, lesser the number of units less will be maintenance cost. But for the system stability and avoid the complete shutdown of powerhouse more than one unit is strongly recommended.

11.6.7 Transportation

The transportation of heavy construction and permanent equipment (turbine runner, generator rotor, stator, transformers) to the site is a matter which needs careful attention. In Case of AHPP, no transportation limitation is found.

11.6.8 Cost effectiveness

Higher the number of units more the E&M and total project cost. In case of 03 units, the difference in energy benefits is very less, however by increasing units from 03 to 04 cost will increase considerably. Thus 03 units are more suitable and cost effective.

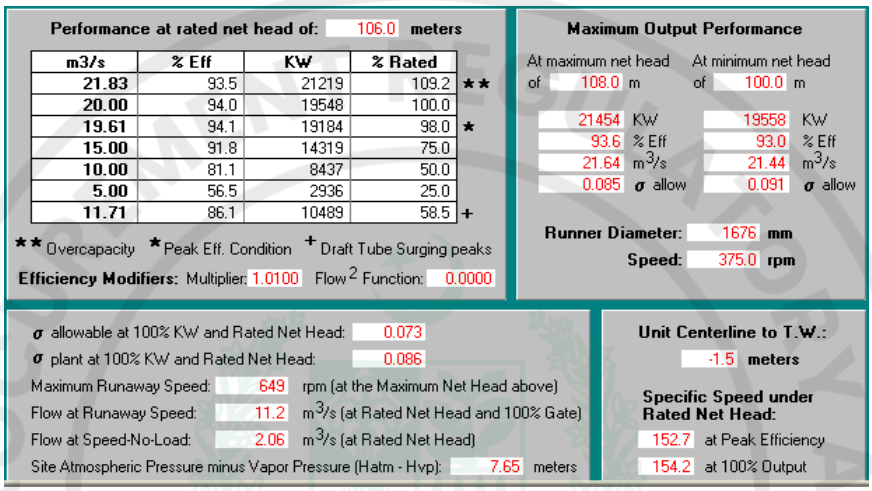
11.6.9 Recommendation

Considering all above parameters/aspects, three (03) units are the most favorable solution from the technical and economical point of view. A summary of key turbine parameters are shown in Table-11.3 below.

Table 11-3 Key Turbine Parameters

Name	Quantity	Unit
Number of Turbines	03	-
Turbine Type	Vertical Shaft Francis	-
Design net head	106	M
Minimum net head	100	M
Maximum net head	108	M
Maximum Turbine Efficiency	≥ 91.5	%
Design Unit Discharge	20	m^3/sec
Design Scheme Discharge	60	m^3/sec
Turbine Rated Output	19	MW
Rated Speed	375	Rpm
Runaway Speed	649	Rpm

All proposed turbines are of Vertical shaft Francis type. The turbines will be directly coupled to the generator rotor.



The direction of rotation shall be clock-wise when viewed from drive end. The turbines shall be capable of giving outputs higher than rated outputs to match the overload capability of the

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

generators. Each turbine shall be designed to give a rated output at rated head at generator terminals with guide vane opening of about 80-85 %. The turbine shall have adequate capacity commensurate with the 10 % continuous overload capacity of the generators.

11.7 TURBINE LAYOUT AND SIZING

The layout and sizing of the AHPP turbine units have been carried out using the in house available computation programs, United States Bureau Reclamation (USBR) manual and computer software TURBNPRO. Details of computation and analysis on computer software TURBNPRO is shown below from Figure-11-5 till Figure 11-11 below:

Performance at rated net head of: 106.0 meters

m3/s	% Eff	KW	% Rated	
21.83	93.5	21219	109.2	**
20.00	94.0	19548	100.0	
19.61	94.1	19184	98.0	*
15.00	91.8	14319	75.0	
10.00	81.1	8437	50.0

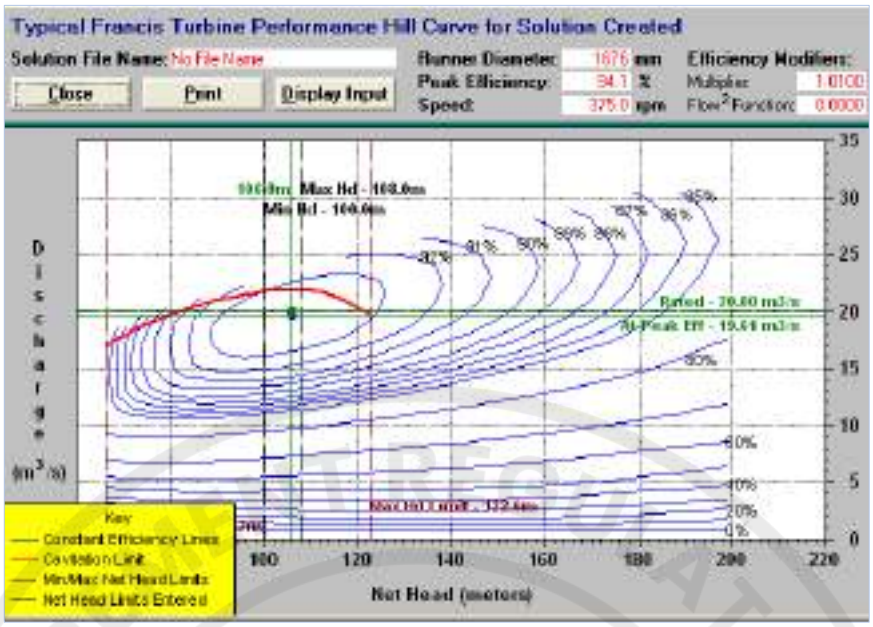

Figure 11-10 Performance Hill Curve

11.8 MAIN DATA

The turbine rated output is expressed by the following equation:

$$P_t = \rho \times 9.81 \times Q \times H_n \times \eta_t$$

Where,

P_t = Turbine out Power (KW)

Q = Discharge (m^3/sec) = 20 m^3/sec

H_n = Rated Net Head (m) = 106 m

η_t = Efficiency of turbine = 91.50 %

$$\mathbf{P_t = \rho \times 9.81 \times Q \times H_n \times \eta_t}$$

P_t = 1000*9.81*20*106*0.915

P_t = 19 MW

Rated Turbine Output at shaft, P = 19 MW

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

11.8.1 Turbine Speed

The main data for comparison of some turbine speeds is made as follows:

Turbine Speed	300 rpm	333 rpm	375 rpm
Runner outlet diameter	1.828 m	1.757 m	1.676 m
Runner weight	9.19 ton	7.91 ton	3.32 ton
Turbine setting approx.	- 2.0 m	- 2.0 m	- 1.5 m
Turbine efficiency	91.2 %	91.1%	91.5%
Turbine Generator weight	28 ton	23 ton	10 ton

Considering the technical and related advantages of high speed units, a turbine of 375 rpm is selected for this project.

Turbine speed = 375 rpm

11.8.2 Runner diameter

Runner diameter = 1676 mm

11.8.3 Runaway speed

The unit Maximum runaway speed as determine by TURBNPRO comes out to 649 rpm, however an accurate value is guaranteed by the turbine manufactures.

11.8.4 Setting

The turbine has to place sufficiently below the tailrace level to ensure that there is an adequate submergence. The proposed minimum setting for all turbines is about -1.5 m.

The turbine setting is determined as follows from the referenced Standards.

$$Z = H_s + b + HL_{tw}$$

$$H_s = (H_b - H_V) - \sigma H_{cr}$$

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Where:

Z	=	Total draft head (m)
H_s	=	Static draft head (m)
b	=	Vertical distance from centerline of distributor to minimum runner diameter
H_b	=	Barometric pressure of water at station site (m)
H_{cr}	=	Maximum head at which turbine operates with full gate for maximum generator output
σ	=	Cavitation coefficient
H_v	=	Water Vapour pressure (m)
HL_{tw}	=	Tail water tunnel loss (one unit operating)

The cavitation coefficient σ, is normally quoted by the turbine manufacturer after undertaking a series of cavitation model tests.

11.8.5 Components Dimensions

The turbine major components dimension and layout have been workout by software TURBNPRO, moreover this data also compare with the similar installations in term of type and size, which have been built in the past. Components Dimensions are shown in Figure-11.4 till Figure-11.7.

11.8.6 Special design criteria

The turbine and its various components shall be designed to operate at a maximum load and to bear the stresses produced corresponding to maximum turbine shaft power output.

11.8.7 Overpressure

The maximum pressure in the spiral casing in the most unfavorable condition of head and sudden discharge, with or without wicket gate closing, will not exceed a pressure rise of about 25%.

11.8.8 Over-speed

The maximum momentary speed rise will not exceed 45% of the rated speed in the most unfavorable i.e. 544 rpm.

11.8.9 Runaway speed

The turbine will withstand the maximum runaway speed in the most unfavorable head and gate condition safely and without any abnormal reaction. Maximum runaway speed is 649 rpm.

11.8.10 Critical speed

The first critical speed of the combined turbine generator unit will be at least 25% higher than the maximum runaway speed.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

11.9 TURBINE MAJOR COMPONENTS

The main parts of the turbine are described as follows:

- Runner
- Shaft
- Bearings
- Guide Vane Mechanism
- Operating Mechanism
- Throat Ring
- Draft Tube

11.9.1 Runner

The runner is the energy conversion element of turbine. Francis runners use stainless steel blades, bands and crowns. Special alloys are also used to minimize erosion. In this project the runner will be a cast or welded construction of 13% chrome, 4% nickel steel. The runner shall be designed and manufactured to operate at any load, head and speed within the limits given, as well as the runaway speed at maximum head with exceeding the allowable stresses and without undue cavitation's and vibration.

All surface of the runner exposed to the flow of water will be carefully machined and finished smooth to the templates.

11.9.2 Turbine shaft and Coupling

The turbine shaft shall be forged carbon steel or alloy steel conforming to IS or other equivalent international standards. Wherever the flanges are integral with the shaft, the same should conform to American standard ANSI-49.1.

The turbine shaft shall be connected to the runner on one side and to the flywheel generator shaft on the other side. It shall be of ample size to transmit torque at rated speed without excessive vibration or any distortion. A renewable and removable sleeve of stainless steel shall be provided wherever the shaft passes through a shaft seal or a gland.

11.9.3 Bearings

The turbine bearings can be:

- The pad type or sleeve type or Babbitt lined, self-lubrication type.
- Anti-friction ball, roller bearings, oil or grease lubricated.

The turbine shall be provided with adequate number of bearings. The bearings shall be designed to withstand operation at maximum runaway conditions with cooling water supply on for a period of not less than 15 minutes and also for operation at normal speed without cooling

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

water supply for 15 minutes. The bearings shall be provided with a dial type or resistance type thermometer and a pressure gauge with provision for alarm annunciation/shut down on excessive bearing temperatures.

11.9.4 Spiral casing

The spiral casing shall be fabricated from welded steel plate/mild steel plates and shall have suitable sections for ease of shipment and to be within transport limitation. The spiral case shall be designed to withstand maximum water pressure including water hammer and shall be complete with anchors, supports, sole plates, turn buckles, hold-down rods, all types of clamps, etc.

11.9.5 Guide Vanes

The guide vanes shall be made from stainless steel. Sleeves of stainless steel at the bearing and sealing surfaces shall be provided, if required. The guide vane bushes shall be of the self-lubricating type with protective seals or shall be suitable for grease lubrication.

11.9.6 Operating Mechanism

The operating mechanism shall have ample strength to withstand the maximum load that can be imposed on it by the most severe operating condition. All working points with relative motion shall be bronze bushed, grease lubricated/ self-lubricated. Means shall be provided for adjusting the position of the individual guide vanes to ensure close contact with adjacent guide vane in the closed position.

Each guide vane shall be individually connected to the regulating ring through suitable levers and links. Shear/ breaking link or some other suitable arrangements shall be provided on each guide vane to protect guide vane and to provide alarm on foreign body getting wedged between guide vanes.

The regulating ring shall be fabricated from welded steel plates. It shall be supported on the outer casing of top/side cover on bronze strips with provision for grease/ self-lubrication.

11.9.7 Guide Vane Servomotor

The guide vane shall be operated by two double acting oil operated servomotors of adequate capacity. The servomotors shall be capable of moving guide vanes smoothly during full opening and closing in required time. Standard available hydraulic cylinders of approved make, proven design and of suitable material can also be used as a servomotor.

11.9.8 Top Cover/ Side Cover

The top/side cover shall be of cast steel or welded plate construction. Suitable stainless steel labyrinth rings or similar sealing arrangements shall be provided in the covers.

11.9.9 Draft Tube

Each turbine shall be provided with a draft tube liner/suction bend of welded construction of structural steel. The draft tube cone shall have machined flange for bolting with the runner chamber. The design of the draft tube shall be such as to ensure the best overall efficiency for the turbine and stable and pulsation-free operations of the machines.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

All components will have state-of-the-art design and conform to the relevant international standards. The turbine construction will enable all maintenance and repair work, which will require standstill of the turbine, within the shortest possible time. All turbine components to be dismantled will be equipped with eyebolts, lugs and / or other devices to facilitate handling, installation and removal. All tools and devices will be delivered, which are specially made and / or require for assembling, dismantling, adjustment and maintenance of the turbine. The scope of spare parts as well as the tests to be performed in the Works and at site will be specified in detail in tender documents.

11.10 TURBINE MODEL TESTS

Model tests are conducted to identify early the characteristics and problems of the prototype and to do the necessary modifications. The verification of the guarantees is more accurate at the test rig than at Site. From the manifold inlet to the discharge pit, the model turbine will be of vertical and fully homologous to the prototype. The model turbine chamber will include all baffles, dummy deflectors and operating rods, air vents and all other fixtures in the runner discharge pit, which will be installed in the prototype. The discharge passage will be included, together with means for measuring the runner chamber water levels.

The model acceptance tests will be performed according to IEC 60193. The preliminary model test report will be submitted by the Contractor latest 28 days prior to the start of the model acceptance witness tests. The turbine model tests will at least include the following items:

- Performance tests to determine the performance characteristics of the prototype for various needle openings and at net heads corresponding to the various flow rates.

- Runaway tests to determine the runaway speed under the operating heads.

11.11 GOVERNOR SYSTEM

Each turbine shall be equipped with suitable electro-hydraulic or electronic governor conforming to IEC No. 308, governor actuator, pressured oil unit and associated control and safety devices. The governor actuator and the pressured oil unit will be arranged on the Turbine Floor, whilst the cubicle containing the digital governor will be next to the unit control board on the Machine Hall Floor. The governor shall be of proven design capable of controlling speed / output under all operating conditions. The governing system shall comprise oil pressure system, governor actuator (Mechanical), governor electronic regulator, speed signal generator, oil pipe lines and deflector position restoring mechanism. The electronic regulating functions of governor i.e., speed / gate setting, deflector limit setting, start, stop, main circuit breaker position, shutdown etc. shall operate the unit in manual mode in case governor electronic regulator is non-operative. Local control unit have the indicators for deflector position, speed of the unit and power generated by the unit.

The control should be possible:

- Locally at the governor for the control of individual components and for maintenance purposes.

- From the main control board for starting, synchronizing, loading and stopping the unit.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- From the control room for supervising the function and operating the unit in connection with the main grid and for the local network.

11.11.1 Governor Head

Each governor head to be assembled in the main control board of the power station shall be equipped with

- Start and stop switches
- Quick shut down
- Speed setting
- Speed drop setting

All necessary buttons, indicators, instruments and limit switches and the control equipment for the automatic start, synchronizing and stopping sequence should be provided.

11.11.2 Electronic Equipment

In recent years the advent of the microprocessor has changed the design of the electronic governors from analogue to digital systems with much more effective man-machine interfaces. The electronic governor control provides functions such as turbine, start / stop, auto-frequency control and automatic load control, and provides interface connections to a main control and instrumentation system. Its monitoring functions include fault detection, alarm annunciation and unit shutdown. The governor also provides facilities for manual control of the turbine.

The electronic equipment is extremely reliable and the digital technology allows continuous self-checking of system operation. As the parameters for each turbine are stored within computer programs, there is no need for printed circuit boards to be pre-calibrated. With a digital system all the data is stored either within memory circuits (EPROMS) or is downloaded from a programming module or central computer. The governor is normally designed to allow circuit modules to be replaced whilst the unit remains connected to the grid. As the mean time between failures is usually a number of years, a large stock of spares is not usually required.

The following functions will be included in the governor:

- Speed control at no load operation.
- Automatic start and stop sequences, including automatic synchronization.
- Power output control; operation at output limitation with power feedback.
- Frequency regulation.
- Load sharing between the units in "joint control" mode.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Quick shutdown in case of mechanical failures.

- Emergency shutdown on electrical failures.

11.11.3 Hydraulic Systems

The main development in hydraulic systems over recent years has been a steady increase in the operation pressure of the governor hydraulic systems. This change has been driven by two factors: cost and size. As the system pressure is increased the cost of the hydraulic system decreases due to reduction in its size. With increasing system pressure, the size of guide van servo-motors, oil pumps, oil piping and tanks decreases. The overall effect of an increase in system pressure is a reduction in the turbine cost although there is some increase in the governor cost. For very large turbines, the oil storage requirements at low system pressures are very large and this has also encouraged the adoption of higher pressures.

One further advantage of reducing the size of the hydraulic system is that more of the equipment can be assembled and tested within the manufacturer's works. This means that site work can be limited to simply connecting a skid-mounted package containing low and high pressure tanks, oil pumps, control valves, etc., to the turbine servomotors. The reduction of site work shortens the installation time and also increases the reliability as there is less opportunity for contamination of the system.

11.11.4 Water Hammer within High Pressure Conduit

Water hammer is a pressure change in a close pipe caused by water deceleration or acceleration for example due to opening / closing of the turbine wicket gate. The worst case for water column deceleration within the power conduit is the emergency shut down of the unit.

For the investigation of the worst case, a check according to the empirical formulae for rigid water column theory by Parmakian, Ray S Quick's water hammer chart and Allievi Chart for determining maximum pressure rise and also United States Bureau of Reclamation (USBR) Table and empirical formulae for determining speed rise due to load rejection must been applied. It shows the order of magnitude of the water hammer for linear closing characteristic of the turbine guide vanes.

11.12 TURBINE INSTRUMENTATION, CONTROL AND SAFETY DEVICES

Each turbine shall be provided with a complete set of instruments, gauges, controls and safety devices for unit control board for monitoring the conditions of the unit during normal running and emergencies. The instruments and gauges for the turbines include, inter alia, pressure gauges, level indicators, temperature and flow indicators, position indicator, indicating lamps for status indication etc. The safety devices shall comprise equipment and devices for sensing abnormal operating conditions, for giving visual and audible annunciation and shut down the unit.

11.13 INLET VALVE

A Butterfly type shut off valve will be required at the powerhouse end at upstream of each turbine. It will allow the penstock flow to be shut off in case of turbine malfunction, maintenance or an emergency.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The valve shall be suitable for all operating conditions of transient and maximum water hammer. The valves shall be operated by oil pressure and closed by oil pressure/counterweight, so that it is capable of being closed under all emergencies. All associated equipment such as servomotors, oil pressure units, counterweights, etc., shall be included in the offer. The valve shall close automatically under normal and emergency shut down conditions. The valve will be complete with inlet pipe, outlet pipe, with expansion joint, by-pass arrangement if required for equalization of pressure on either side of the valve, etc.

The main Data for these valves is as follows:

Valve type	Butterfly
No of valves	03
Diameter	1.83 m
Sealing system	Cast steel
Operating system	Pressure oil

11.13.1 Operating Mechanism

The valve rotor will be driven by an oil servomotor, which will be fixed on the valve body and supplied with pressured oil by its own hydraulic unit. In comparison with servomotor operated by headwater taken from the penstock and closing by weight and opening by pressured oil or water, opening and closing by pressured oil is the most economical solution and the easiest for maintenance. The seal rings will be moved by pressured water taken from the penstock, which will be filtered.

The service valve in the by-pass will be operated by the pressured oil provided by the same hydraulic unit as for the oil servomotor. Opening and closing of the butterfly valve will be possible at the minimum operating level in the reservoir and at the minimum operating oil pressure of the hydraulic unit.

11.13.2 Control and Safety Devices

The butterfly valve will be designed for both fully automatic remote control and manual control locally. Normally, the butterfly valve will be controlled by the automation and control system of the power plant. However, it is possible to operate locally each valve step by step.

The operation of the butterfly valve will be so interlocked hydraulically and mechanically that it will be impossible to move the sealing rings to the closed position, unless the valve rotor is in the “closed position”. On the other hand, it will be impossible, too, to turn the valve rotor towards the open position unless the seal rings are unsealed. A manual closing device will be installed on the Turbine Hall floor. For safety reason, the maintenance seal can be mechanically locked at the closed position. Furthermore, it will only be possible to open locally. At the fully open and close position, the valve rotor can be mechanically locked.

All components will have state-of-the-art design and conform to the relevant international standards. The valve construction will enable all maintenance and repair work, which will require standstill of the turbine, within the shortest possible time. All valve components to be

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

dismantled will be equipped with eyebolts, lugs and / or other devices to facilitate handling, installation and removal.

All tools and devices will be delivered, which are specially made and / or required for assembling, dismantling, adjustment and maintenance of the valve. The scope of spare parts as well as the tests to be performed at the Works and at Site will be specified in detail in the tender documents.

11.14 AUXILIARY SYSTEMS

The auxiliary systems in a power plant have a vital role in the power plant's successful operation. Auxiliary systems shall include the various functions like plumbing works and fixtures, sewerage system, oil handling, drainage, detecting and suppressing fire, compressing air, Heating and ventilation of powerhouse, handling of various parts, workshop facilities etc.

To have a well-functioning, easy to operate, and easy to maintain power plant, all the auxiliary systems have to be carefully considered and conceived. A major design concern for auxiliary installations (such as compressors, strainers, and pumps) is their location, performance and maintenance access. The items requiring maintenance or monitoring shall be installed in easy-to-access areas for convenience

11.14.1 General

The sewage, sanitation and potable water system for Attabad powerhouse includes the following systems:

- Plumbing works and fixtures
- Water supply system
- Sewerage system

11.14.2 Plumbing Works

The plumbing works will include glazed earthenware water closets, wash hand basins, urinals, overhead showers, kitchen sinks, electric water heaters etc.

11.14.3 Water Supply System

The water supply system will include hot and cold water supply piping, pressure filtration unit and water treatment with ultraviolet disinfection tube having a capacity of 25 liters per minute, valves and other fittings.

Two pumps each of capacity 50 l/min at 1 bar to operate one as main and the other as standby, will pump treated water to the potable water storage tank for further distribution.

11.14.4 Waste and Sewerage water

Septic tank for lavatory disposal has been foreseen, the settled sludge will be periodically removed by using sludge pump or trolley and the sewage will be drained to downstream, away from the tail race pit through drain pipe. The sewerage and drainage system will include a network of C.I spun pipes, C.I fittings, C.I floor traps man hole frames and covers, gratings,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

glazed earthen ware, soil and waste pipes, etc., to be provided on the various floors of Control Block and a steel sewage septic tank of capacity approximately 6000 liters buried underground outside the powerhouse.

11.14.5 Dewatering and drainage system

Depending on the general layout, the station drainage system would be required to handle waters from the powerhouse and from several other equipment and accesses located below the maximum infrequent tail water level. These will include:

- Cooling water of minor mechanical systems, such as: compressors, governing systems and alike.
- Water leaking to the turbine pit through the shaft seals and wicket gate stem seals.
- Water used for cleaning the floors of caverns and galleries.
- Seepage of water to the caverns, galleries accesses and tunnels with the inflow to fulfill geotechnical requirements to be established at the design stage.
- Water from pressure relief perforations and systems to be established at the design stage.
- Any releases from the sprinklers of firefighting water system.

The dewatering and drainage system shall be provided, which shall include all structural components and equipment required for dewatering penstocks/ draft tube for maintenance purpose, and for dewatering all seepage of structures and equipment.

Dewatering of the units will be required during scheduled or unforeseen maintenance of any of the units and incase of leakages from valve on bypass line connecting upstream of inlet valve to draft tube.

A gravity drainage system consists of various equipment drains (like compressors, gland leakage etc.) and floor drain, condensate that drain to a main sump / pit, located at lowest elevation of the Power house. The water in the sump shall be pumped into the tailrace. Pumps shall be sized to meet the required estimated seepage and drain water. Two submersible pumps are recommended. One pump will work as standby. These pumps shall operate alternatively for equal wear and tear.

11.14.6 Compressed Air System

A compressed air system will be provided for the service and maintenance purpose. The capacity of the system shall be sufficient to cater to all the generating units. The compressed air system shall be of the automatic start-stop design operating under pressure switches control sensing the pressure in the receiver. The compressors will be electrically driven.

The whole system of compressed air supply shall comprise 03 systems, as follows:

- Compressed air for workshop equipment.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Compressed air for governors pressure oil tanks.
- Service air (for generator brakes and operation of equipment etc.)

Each air system shall be supplied complete with all piping, valves, fittings and accessories for all required connections.

11.14.6.1 Design Criteria and Operation Conditions

Operation pressure will be about 0.8 MPa. Two (2) identical air-cooled compressors of screw type and two (2) identical air accumulators will be provided, one for service, and other as stand-by. They will be placed on the turbine floor.

- The compressed air system will have following main components:
- Two (2) identical air-cooled compressors of screw type, each with a delivery capacity of not less than 80 m^3/h of atmospheric air.
- Two (2) identical air accumulators, each with a capacity of 1.0 m^3.
- Distribution piping throughout the powerhouse with connecting taps, to the air receivers for the mechanical brake of the generators and to other services.
- Monitoring, control and safety devices.

All components will have state-of-the-art design and conform to the relevant international standards. The scope of spare parts as well as the tests to be performed in the Works and at Site will be specified in detail in tender documents.

11.14.7 Oil Handling System

Two oil handling systems will be provided at the power plant, which are:

- Turbine oil handling system.
- Transformer oil handling system.

11.14.8 Turbine Oil Handling System

For ease of handling and filtration of turbine and governor oil inside the powerhouse, the equipment is laid out on turbine floor, with oil storage tanks and the filtration plant located under the erection bay.

The oil handling system will have the following main components:

- One (1) oil filtration plant (Stationary type)
- One (1) oil filtration plant (Mobile type)
- One (1) clean oil transfer pump (Mobile type)
- One (1) dirty oil transfer pump (Mobile type)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Two (2) clean oil storage tanks
- Two (2) dirty oil storage tanks
- Supply and return pipe work
- Control and safety device
- Oil testing device

The oil storage tanks will be sized to accommodate the oil of governor and all bearing of one unit. The oil treatment plant will be designed for carrying out degassing, dewatering, filtering and drying of the lubricating oil and pressure oil of the governor to prolong the life of plant. The capacity of the oil treatment plant will be 3 m^3/hr maximum. Mobile oil treatment plants will be provided with suitable rubber hose pipes and power cables. Each mobile unit will have a capacity to purify about 0.2 m^3/hr oil.

The steel pipe work will be designed for a working pressure, with supply and return headers connecting the filtration plants, oil storage tanks and the oil reservoirs of the unit.

11.14.9 Transformer Oil Handling System

The transformer oil handling system will have following main components:

- Two (2) oil purification and treatment plants (Mobile type).
- Two (2) oil transfer pumps (Mobile type).
- One (1) set of oil drums in enough quantities to drain one transformer completely.
- One pick-up to transport the oil drums and other equipment from and to the storage area and the powerhouse.
- One (1) fork lifter two (2) ton capacity.
- Controls and safety devices.
- Oil testing devices.
- Two (2) sets of rubber hose pipes about 15 m long, with connectors at both ends for connecting the purification plant / transformer pump with the transformer.
- The capacities of oil purification plants and transformer pumps will be approximately the same as those for the turbine oil handling system.

11.14.10 Heating, Ventilation and Air Conditioning System

Necessary arrangement for Ventilation, cooling and heating will be provided, according to powerhouse area requirements.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

PUBLIC PROCUREMENT REGULATORY AUTHORITY
(PPRA)
EPADS

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

HVAC system will be designed in view of the following objective:

- To maintain indoor temperature at a pre-determined value by extracting heat from the indoor environment. The plant will have a capacity in terms of heat extraction rate equal to maximum anticipated heat input to indoor environment from electrical-mechanical equipment, lighting, people and conduction from fresh air.

- To maintain indoor relative humidity at a pre-determined value for areas such as control room, computer room, administration areas, electrical equipment rooms etc. by condensation of moisture in air stream.

- To provide clean air to conditioned apace by filtration of re-circulated and outside (fresh) air.

- To pressurize the building up-to 0.3 mbar to prevent infiltration of uncontrolled outside air.

- To provide winter heating in areas such as control room, administration areas, computer room etc. by adding heat to indoor environment. Relative humidity will simultaneously be controlled by adding moisture whenever required.

- To recover equipment heat dissipation in winter and to use it for space heating where possible.

The proposed air conditioning system for this project calls for providing year round air conditioning and ventilation to provide comfortable and required ambient conditions for people and sensitive equipment in the specified areas.

The design criteria are, to maintain indoor temperatures at 22 ~ 24^{o}C. In order to maintain that temperature in offices and control room, an independent air conditioning system shall be provided. Layout, dimensioning and arrangement of air-conditioning equipment will be defined during preparation of construction drawings of powerhouse building

11.14.11 Fire Protection System

The fire protection system is an important auxiliary system for any powerhouse. This system mainly consists of the equipment required for detecting and extinguishing fire in the powerhouse. The fire protection systems will be provided to extinguish fire of the following equipment and areas:

- Generators

- Transformers

- Oil storage rooms

- Computer and control rooms

- Remote computer control terminal units

- Office and miscellaneous-spaces, electrical and control equipment galleries

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Auxiliary and powerhouse equipment and maintenance workshops
- Diesel generator rooms located at head works.

There will be three common systems for fire protection:

- Water Spraying System
- CO2 Fire Protection System
- Potable Fire Fighting cylinders

In this system a group of Carbon dioxide (CO_2) filled cylinders are arranged in series at any suitable location and connected by a common piping system for spray through nozzles set in each generator. The system shall operate automatically with heat detecting elements. It is also possible to operate this system manually in case of failure of automatic system.

Moreover, Carbon dioxide (CO_2) filled fire extinguisher will also be placed at different floors to extinguish electrical fires. Oil storage rooms shall also be provided with CO_2 filled cylinders with auto release system initiated by smoke and fire detectors installed in the room.

Fire hydrants at different locations in control building, service area and administrative areas are to be provided. Mobile fire extinguishers shall be placed at most wanted locations in powerhouses. In addition, the power station will be provided with several taps for fire hoses. The water for the firefighting system shall be taken directly from upstream side.

Transformer fire is most common in hydro plants, thus special care and arrangement is required to overcome. Water deluge system seems to be the most successful, safest and from most aspects preferred method for fighting transformer fire. The water will be used from service water supply tank having desired water pressure with back up of fire / booster pump.

11.14.12 Standards and Regulations

All fire protection installations shall be designed, in accordance with the international NFPA-Codes and Standards, mainly NFPA 851, Recommended Practice for Fire Protection for Hydroelectric Generating Plants, (Latest Edition).

The design of fire protection installations shall also be in accordance with local regulations and requirements from the authority having jurisdiction.

11.14.13 Particular Requirements

11.14.14 Survey of systems

The firefighting systems to be provided are indicated in the following table as a minimum. Number and location of the various installations and systems shall be determined by the Contractor as per applicable code during detail design, subject to the Employer's / Engineer's approval. The Contractor shall, however, add and include any areas / items not listed in the table in order to cover fire protection for the entire plant.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 11-4 Survey of Fire Protection System to be Installed

Sr. No.	Building /Area / Equipment to be Protected	Fire Fighting Systems	Fire Detection Systems
1.	**Power House Building**		
1.1	Machine Hall	Portable Dry powder fire extinguishers & one mobile 30Kg clean agent extinguisher	Manual fire alarm stations
1.2	Generator	Automatic & electrically interlocked CO2 gas fire suppression systems	Smoke / Heat detectors, generator differential relay.
1.3	Turbine Floor	Portable Dry powder fire extinguishers	Manual fire alarm stations, Smoke detectors
1.4	Inlet valve Floor	Portable Dry powder fire extinguishers	Smoke detectors, Manual fire alarm stations
1.5	Unloading Bay Floor	Hydrant Hose stations, Dry powder Fire extinguishers	Manual fire alarm stations
1.6	Oil Handling & compressor Plant Room, Water treatment room, HVAC room, Mechanical store	Hydrant Hose stations, Portable dry powder Fire extinguishers	Smoke detectors, Manual fire alarm stations
1.7	Elevator Hoist Machine Room	Portable dry powder extinguishers	Smoke detectors, Manual fire alarm system
1.8	Maintenance Engineers, Conference room, Operational Manager room, document room and Prayer room	Portable clean agent fire suppression system	Smoke detectors, Manual fire alarm stations
1.9	Cable Tunnel	Automatic water spray system	Smoke / heat detectors
1.10	Control room, relay room, SCADA and telecommunication room	Portable clean agent fire suppression system	Smoke detectors, Manual fire alarm stations
1.11	Workshop, Battery Room & Switchgear room	Portable dry powder fire extinguisher.	Heat / Smoke detectors Manual fire alarm stations
1.12	Corridors and Lobbies	Portable dry powder fire extinguishers	Smoke detectors, Manual fire alarm system
2	**GIS Building**		
2.1	Switch yard	Portable fire extinguishers	Smoke detectors, Manual fire alarm system
2.2	Cable Spreading Room	Automatic water spray system	Smoke / Heat detectors
3	**Diesel Generator Room**	Portable dry powder fire extinguishers	Smoke / Heat detectors, Manual fire alarm system
4	**Penstock Valve House**	-do-	-do-
5	**Power Intake Control Room**	-do-	-do-
6	**Transformer Bays**		
6.1	Automatic water spray system and one mobile 30Kg portable dry powder extinguisher	Smoke / Heat detectors, Manual fire alarm system	Automatic water spray system and one mobile 30Kg portable dry powder extinguisher
7	**Water Storage tank Pump House**	Portable dry powder fire extinguishers	Smoke / Heat detectors manual fire alarm system

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

11.14.15 Structure Fire Protection

Fire Areas

In order to avoid an uncontrolled fire, spread inside a building or a tunnel, which would result in a considerable or total loss of the building and equipment, and to provide safe escape routes for the personnel, the building / tunnel shall be subdivided into various fire areas, separated by approved fire resistant barriers and elements.

Fire walls, ceilings and partitions shall have a fire resistance rate of not less than 2 hours.

All penetrations for electrical cables or pipes in fire resistant walls or ceilings shall be sealed with approved seals.

Firefighting Pump

One electric motor driven fire pump and one electric motor driven stand-by fire pump, located in a pump house adjacent to the water storage tank, shall draw fire fighting water from the tank and supply it through the fire service main to the hose stations and water spray fixed systems. One electric motor driven jockey pump with a capacity of approx. 3 l/s shall also be provided to keep the line pressure of 5 bars.

The fire pump shall have a capacity of approx. 40 l/s at a delivery head of approx. 6 bars. The final capacity of the firefighting pump shall be verified during detail design.

The firefighting pump unit shall be connected to the safe station power supply.

The pump shall start automatically upon water flow and / or pressure drop in the fire service main.

A fire service main system shall be provided, to serve outdoor hydrants, indoor hose stations and water spray fixed systems with firefighting water.

Next to each outdoor hydrant, a weather resistant, properly ventilated and red painted fire hose cabinet shall be provided, containing four (4) fire hoses DN 65 (21/2") with couplings and two (2) jet / spray branch pipes.

Each indoor hose station shall be housed in a wall mounted or self-standing cabinet, which shall contain a valve with reducer, instantaneous couplings, swiveling hose reel and one 30 m long non collapsible fire hose with readily attached branch pipe.

Water Spray Fixed Systems

The water spray fixed systems shall be designed, installed and tested in accordance with NFPA15.

Complete systems will be provided with all components required for automatic operation, normally released via the fire detection and fire alarm system. Manual release will also be possible.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The automatic operation for opening the deluge valves for the spray systems shall be initiated either by the detection of 2 heat or smoke detectors of 2 different detection lines (2 out of 2) or the transformer buchholz relay.

The deluge valve stations will be located adjacent to but not inside the same fire area they shall protect.

The following specifications shall be observed for the firefighting system of the transformers.

- The water shall be sprayed at a rate of not less than 10 l/min m2 of the projected area of rectangular prism envelope of the transformer.

- A pipe cage made of galvanized steel pipe with all necessary spray nozzles shall be installed around each transformer.

Total Flooding Carbon Dioxide Fire Extinguishing Systems

The total flooding carbon dioxide extinguishing systems shall be designed in accordance with NFPA 12, standard on carbon Dioxide extinguishing systems (latest edition) and will be adopted for the fire protection of Attabad HPP generators.

Complete system shall be designed, for automatic operations normally activated by the fire detection and alarm system.

In this system the CO2 gas is stored in cylinders. It is delivered to distribution nozzle through a system piping network in the fire protection area. Critical to the functioning of system is the fire detection and control network. Smoke detectors sense the presence of fire in the protected facility. The detection and control panel then sounds and alarm, shuts down air handlers, disconnect power from the protected equipment and then release agent into the protected area.

Fire Extinguishers

The selection, installation and testing of portable fire extinguisher shall be in accordance with NFPA-10 for initial firefighting. Portable fire extinguishers with capacities of 6 kg chemical dry powder, for rooms containing electrical equipment with capacities of 5 kg clean agent, shall be provided and placed in the rooms and buildings at strategic locations and next to exits.

In addition to the portable extinguishers, two mobile 30 kg clean agent, and two mobile 50 kg dry powder extinguishers, mounted on wheeled hand carts and furnished with 6 m hoses, shall be provided and located in the machine hall of the powerhouse and GIS floor and diesel generator room.

Other equipment like fire blankets, first aid boxes and rescue tools will be provided as required.

11.14.16 Powerhouse Crane

The powerhouse crane will be a bridge crane with a main hoist, which can serve any requirements for lifting and moving of heavy components during installation, maintenance work and operation, the generator rotors being the heaviest components. AHPP is equipped with 03 Vertical Francis turbines.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The main crane hook shall be capable of lifting the tallest component of the transport vehicle and both the main and auxiliary hooks should be capable of reaching as far down as required to serve the inlet valve floor.

The hoist is mounted on a trolley of compact design enabling minimum operational hook distance from the walls and maximum lifting height. The main hoist is equipped with one hook, cable and drum, with possibility of changing the corresponding values of lifting capacity and hoisting speed with push- button from the crane driver's cabin.

Provision shall be made on the powerhouse roof above the erection bays for easy replacement of the trolleys.

Design Criteria and Operation Conditions

The overhead bridge crane will be designed according to the well reputed international standards likes EN, DIN, FEM, etc.

The overhead bridge crane will have a main hook and an auxiliary hook with a preliminary capacity of 80 t and 20 t, respectively. The main hook will be used for lifting heavy pieces like generator rotor and butterfly valve, whilst the auxiliary hook will be utilized for erection and maintenance work of small parts like rotor poles, servomotors, heat exchangers, etc.

Usually, the heaviest and the tallest piece to be handled by the main hoist is the generator rotor with shaft, and its weight and height will be finally fixed by the generator supplier. Thus, the capacity of the main hook and height between the powerhouse crane and the erection bay floor shall be optimized during the implementation stage.

The powerhouse crane will have the following main parameters:

Rated lifting capacity	main hook	80	t
	auxiliary hook	20	t
	Span	17.5	m
	Hook height	8.8	m
Lifting height (total)	main hook	17.5	m
	auxiliary hook	22	m
Bridge traveling speed	normal	20	m/min
	creeping	0.6	m/min
Trolley traveling speed	normal	15	m/min
	creeping	0.6	m/min
Main hook lifting speed	normal	1.2	m/min
	creeping	0.1	m/min
Auxiliary hook lifting speed	normal	40	m/min
	creeping	0.5	m/min

The crane will be controlled from an operator's cabin, provided at the upstream end of the bridge.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

11.14.17 Mobile crane

In addition to powerhouse bridge crane, suitable capacity mobile crane is also provided for:

- Erection of the transformer
- Erection of the machine hall crane
- Loading and unloading the equipment

11.14.18 Power House Elevator

General

One elevator has been foreseen at power plant to be used for transportation of goods from service bay to the equipment gallery and for transporting the passengers from the control room to the inlet valve gallery with electrical equipment in the erection bay and with guide rails for cabins and counterweights complete with all anchorages, bumpers, etc., and all accessories necessary for the elevator to be complete.

Main Data for Powerhouse Elevator

Number of elevators	One (1)
Capacity	13 persons / 1000 kg
Lifting and lowering speed approx.	1.6 m/s

For the design aspects of the elevator, reference shall be made to EN 81, A.N.S.I A17, BS 5655 or other equivalent standards.

The design of the elevator shall meet the following requirements:

- Driven by electric hoisting machine including cable and counter weight.
- Power supply 3 phases 400 v, 50 Hz.
- Shaft doors of the automatic sliding type for access to the elevator.
- Electronic door detectors as safety device for cabin doors.
- Smooth acceleration of cabin.
- Accurate floor landing / leveling without jerking and jumping.
- Continuous operation and high start / stop frequency without overheating of hoisting machine.

The elevator shall be provided with control and safety devices, preventing operation:

- Under overload conditions.
- With open shaft doors.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The cabin control and panel shall be equipped with:

- Push button plates.
- Floor indicator and moving direction indicator.
- Safety push button for emergency stop and acoustic alarm in the central control room.
- Key locked switch for manual control of cabin position.

The panels at the shaft doors shall be provided with:

- Push button plates.
- Direction indicator.
- Gong signal indicating arrival of cabin.

11.14.19 Workshop Equipment and Tools

The complete maintenance workshops will be provided inside the powerhouse for preventive maintenance and repair of powerhouse equipment. The maintenance workshop will consist of followings:

- Electric shop
- Machine shop
- Portable equipment

Workshop equipment and tools should be sufficient to perform the day to day maintenance requirements such as:

Necessary tools for components repair or renewal which do not need specialized skill or experience like welding machine, portable drill machine, small lathe, electric grinder etc.

All special tools, slings, lifting devices, jacks, turn buckles, foundation plates/ bolts, etc. required for erection of the equipment shall be listed and supplied. First filling of oil and grease (if applicable) with 10% extra quantity (included in the overall scope) shall be supplied along with equipment. Welding electrodes as required for site welding and paint for finishing coat shall be supplied by the contractor.

A tentative list of the workshop machinery is as under:

- Gap bed heavy duty lathe
- Gap bed medium duty lathe
- High precision bench lathe
- Shaping machine

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Radial drilling machine
- Drill stand
- Pedestal grinder
- Bench mounted grinder
- Hydraulic press
- Black smith forge
- Machine hacksaw
- Portable electric welding machine
- Pipe bending machine
- Anvil
- Sheet metal sheer
- Dry acetylene welding equipment
- Quenching tank
- Tool cabinets
- Tool room racks
- Lockers
- Metal working benches
- Electrical working benches
- Hand tools
- Air operated tools
- Platform trucks
- Wood saw machine

11.15 HYDRAULIC STEEL STRUCTURE

11.15.1 General

This section introduces the function and / or performance criteria and the derivation of the key dimensions of main components of the hydraulic steel structures which will be installed in the various civil structures of the Attabad Hydropower Project, namely:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- The power intake gates
- The power intake trashracks and cleaning machines
- The power intake stoplogs
- The auxiliary hoisting equipment
- The pressure shaft
- The surge shaft and
- The draft tube gate equipment

11.15.2 Power Intake Gate Equipment

Intakes for power generation serve to provide hydraulically efficient water inlets to the water passages leading to the powerhouse. The passages may consist of conduits embedded in dams, excavated as tunnels, constructed as free-standing penstocks, or as short concrete passages between intakes constructed integrally with the powerhouses.

Power intakes must control the flow into the headrace tunnel during filling of the waterway and isolate the reservoir from the waterway for inspection and maintenance of the waterway and automatically close into and up to maximum flow to protect the waterway and power station in the event of a major breach in the waterway downstream of the power intake.

11.15.2.1 Selection of Gates:

The type of gate to be adopted depends mainly on the size of the opening, the head on the gate, and the operating conditions (corresponding to the following circumstances).

1. If the gate must open and close under full operating head conditions with flow through the intake.

2. If the gate is only required to operate as a guard gate under no flow balanced head conditions.

Generally, a fixed wheel gate or slide gate is used. However, a high pressure gate, caterpillar gate, or a high pressure radial gate is used when the water head is high. A general comparison of slide gate and fixed wheel gate is provided below:

11.15.2.2 Slide Gate

The slide gate is the simplest type of flat gate. It consists basically on a gate leaf that slides alongside guides embedded or fastened to the concrete. The leaf

is provided with sliding surfaces, usually metallic, which under tight contact at the bearing surfaces act as seals. Since it requires little maintenance, the slide gate is largely used as a control device in irrigation canals, sewage works, bottom outlets and small intakes and reservoir spillways.

Other distinguished characteristics of the slide gates are the uniform transmission of the hydrostatic load to the concrete and the absence of vibrations in partial openings due to the

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

large friction forces developed between the sliding surfaces. This feature is highly desired for bottom outlet gates. On the other hand, the slide gate is not recommended for installations requiring closure by gravity, due to the large friction forces created which is a major drawback for an intake gate.

11.15.2.3 Fixed Wheel Gates

High-head fixed-wheel gates are installed in recesses built in intake structures or in the face of concrete dams, at the upstream ends of outlets or penstocks. Since the primary use of these gates is to provide emergency shutoff of water to protect the penstock and downstream equipment, the preferable location of such gates is near the entrance. Therefore, fixed wheel gates is a suitable option for intake gates of Attabad HPP.

11.15.2.4 Functional Requirements & General Arrangement

Two power intake conduits are proposed for tunnel. Immediately upstream of each intake gate is provision for a stop log. It will be lowered when inspection or maintenance of the intake gate is required. The stop log will be raised and lowered by a rail mounted gantry crane.

A trash rack will cover the entrance to each power intake. The bars of the trash racks will be spaced so as to block floating debris large enough to damage the turbines. This way floating debris is prevented from entering the waterway.

A trash rack cleaning machine mounted on rails on the intake structure deck will remove trash and debris collected by the trash racks.

The equipment at power intake will be designed to meet the following functional requirements:

- Two hydraulically operated fixed wheel gates will be installed, one on upstream of each intake tunnel.
- These will be capable to close under full flow in the tunnels in an emergency, if the penstocks fail or turbines over speed.
- These gates will be designed to self-lower under gravity and hydrodynamic forces (down pull). These gates will be used for emergency protection of turbines and penstocks (and will overtake the role of turbine shut-off valve).
- The gates hoisting system will be operable from local control panels as well as from power intake control room.
- Trash racks will be installed at power intake structure to prevent entry of large size trash into the tunnels and clog the turbines.
- A gantry crane operating on a runway spanning the entire structure will be provided for maintenance of the intake gates.

11.15.2.5 Fixed Wheel Intake Gate

Typically, a fixed wheel type gate is used, and it generally consists of the following assemblies:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- The gate leaf assembly, which includes the skin plate, supporting beams and girders, bracings and rubber seals.
- The wheel assembly includes the main and side rollers, lubrication provisions, and mounting brackets.
- The embedded seal path assemblies include the side seal, bottom sill, and anchors.
- The hoist tower and bridge assembly for supporting the gate hoist system.
- Hydraulic Hoist and wire rope hoist system.

11.15.2.6 Gate Leaf

The fixed-wheel gate is certainly the most common type of gate and basically consists of leaf, wheels, shaft and seals. In general, leaf is formed by a flat skin plate and stiffened by horizontal girders and ribs. On each side of the leaf, the ends of the horizontal girders are welded to a vertical girder. Wheels are mounted on shafts fixed laterally to the leaf on the vertical girders and have the double function of reducing the friction forces and the transmission of the water load to the embedded parts. Submerged fixed-wheel gates have seals on all four sides. Seals on dam face gates frequently surround the opening like a picture frame.

Upstream sealing gates have been chosen as they minimize down-pull during closure into flow and provide easy access for inspection of the downstream side of the gate when the gate is closed. The fixed wheel gate will be of welded steel construction with upstream skin plate reinforced by horizontal and vertical members/beams. If necessary, the skin plate assembly will be divided into sections for ease of transportation and handling at the site. These sections will be field assembled by bolting and seal welding.

The gate will be provided with downstream J-type double stem side and top rubber seals with fluorocarbon cladding. A flat bar type rubber seal will be mounted at the bottom of the skin plate on downstream side. Wheels will be with corrosion resisting steel rim mounted. Wheels will rotate on stainless steel spherical bearings (or self-lubricated bearings).

In the steel lined gate section, the guiding parts and sealing facilities of the gates will be integrated. Above the discharge openings, provisions will be made for continuing the guiding parts and sealing facilities in steel lined slots. The steel lined slots will extend up to the equipment room level. The slots will be closed with pressure cover plates or so-called bonnets.

Each gate will be operated by one oil-hydraulic servomotor. The servomotors will be mounted on the bonnets. For each set of maintenance and service gates a common oil pressure unit has been considered. In order to promote safety, the oil pressure units will be interconnected to each other. With this is arrangement it is possible to serve all gates by one oil pressure unit. The design and performance criteria of intake gate is summarized here below:

Table 11-5 Design and Performance Criteria of Intake Gates

Type of gate	Fixed wheel gate
No. of gate openings	2

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

No. of intake gates at the Power Intake	2
No. of embedded parts at the Power Intake	2
Gate operation	Hydraulic cylinder
Operating Speed	0.3 – 0.5 m/min

11.15.2.7 Gate Hoist

Each gate hoist will include a hydraulic cylinder, pipes, hoist support, servomotor, hydraulic power unit, piping, gate position indicator, electric control panel for command and signaling.

Each Fixed Wheel Gate will be provided with one hydraulic hoist. The hoist will be designed to have enough lifting force to lift the gate under any foreseeable operating conditions. Hydraulic oil for raising the gate will be supplied by motor driven oil pumps. Two oil pumps per gate will be provided to ensure reliability. Each oil pump will be rated to supply oil at the required pressure and rate to lift the gate at the maximum lifting speed selected for the gate. Lowering of the gate will be accomplished by gravity i.e. by weight of the gate itself. However, the hydraulic hoist would be able to push the gate down in case the closure resisting forces increase. Provision will be made for normal operation of the gate at all reservoir levels. The design and performance criteria of the Gate Hoist is summarized here below:

Table 11-6 Design and Performance Criteria of Gate Hoist

Type of hoist	Hydraulic
Power equipment for gate operation	415 V from Power Station
No. of hydraulic hoist cylinders per gate	1
Gate handling for repair and maintenance	By gantry crane or mobile crane

11.15.2.8 Gate Hoist Control System

A hoist control module will be provided with each gate, which will control the operation of the hoist. It will include hydraulic and electrical controls. A local control panel will be provided near each gate and a common remote control panel for all power intake fixed wheel gates will be installed in the local control room. The remote control panel will include one selector switch for each gate. The selector switch will provide two operating modes i.e. normal and maintenance.

Provision will also be made for emergency closure of the intake gate from the powerhouse central control room for the protection of turbine against sustained speed if the governor over malfunctions.

11.15.2.9 Embedded Parts

Embedded parts for the guard gate will include anchorages for hoist cylinder, side and top seal bearing plates and guide bars, rails and sill beams. The side and top sealing surfaces will consist of corrosion resisting steel plates embedded in concrete. The bottom sealing surface will also be corrosion resisting steel plate attached to a structural steel sill beam embedded in

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

the concrete floor. The embedded parts will be installed in block outs and adjusted by means of erection studs attached to the welding pads embedded in first stage concrete.

11.15.2.10 Stop Logs

Two stop logs for the two intake gates will be provided. Stop log slots, guides and other embedded metal work will be installed in the piers upstream of each intake gate to guide and finally seal the stop log when it is in the closed position. Exposed parts of the embedded metal work will be cladded with corrosion resistant steel cover plate.

The stop log will be of welded construction with a downstream skin plate reinforced by vertical and horizontal girders. It will have wedge type bottom seals and 'J' type side seals. Guide shoes will be provided at the top and bottom of each side of the stop log to engage the guides embedded in the concrete. The stop log will be designed to be handled by a lifting beam and gantry crane. A filling valve activated by the lifting beam will facilitate balanced head conditions across the stop log before rising. The design and performance criteria of the stop logs is summarized here below:

Table 11-7 Design and Performance Criteria for Stop Logs

Type	Vertical lift
No. of Stop log	2
No. of stop log embedded parts	2 set
Handling	By lifting beam and gantry crane or mobile crane

11.15.2.11 Gantry Crane

One gantry crane will be provided at the power intake. The crane will be an electrically operated outdoor type, with an operator's cab located on the upstream side and raised above the deck for ensuring good visibility of all crane operations. The gantry crane will operate on rails extending over the full length of the intake deck. The crane will be required to handle the service gates and for reparation and maintenance activities within the intake shafts.

A lifting beam equipped with two automatic grappling hooks for setting and removing the stop log will be provided. After the hooks have engaged the stop log, the lifting beam will activate the filling valve, allowing water to flow through the stop log, filling the cavity between the stop log and the closed intake gate so that the stop log can be raised by the gantry crane under balanced pressure condition. The design and performance criteria of the Gantry Crane are summarized in the following table:

Table 11-8 Gantry Crane and Lifting Beam

Type	Electrically operated
No. of gantry cranes	1
Hoist capacity	25 ton
No. of lifting beam	1

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

11.15.3 Trashracks

Trash racks and safety grates are a critical element of outlet structure design and serve several important functions. When properly designed, installed, and maintained trash racks.

Keep debris away from the entrance to the outlet works where the debris will not clog the critical portions of the structure;

Capture debris in such a way that relatively easy removal is possible;

Trash racks can serve these purposes without interfering significantly with the hydraulic capacity of the outlet (or inlet in the case of conveyance structures) (ASCE, 1985; Allred-Coonrod, 1991).

The trashracks will prevent the ingress of debris and floating matter into the power conduit, which could block or damage the generating units.

The trashracks will be of the non-withdrawal type, consisting of fixed trashrack panels supported by streamlined cross beams. The trashrack panels and the corresponding supporting structures will be designed to withstand the design pressure with a safety factor of 1.5.

For condition monitoring of the trashracks, the differential pressure across the panels will be measured. An alarm will be triggered when the trashracks are unduly clogged, requiring action by the trashrack cleaning machines.

11.15.4 Trashrack Cleaning Machines

One trashrack cleaning machine (TRCM) of the cable operated type have been foreseen for installation on the deck level 2424.00 m.a.s.l. of the power intakes.

TRCM will consist basically of a steel gantry structure including the rake carriage, the bucket and the revolving apron as well as the associated hoist and control mechanisms. In addition, an articulated hydraulically operated arm with grapping hook will be provided.

The TRCM will be suitable for all purpose cleaning of the trashracks while operating under flows of 100 m^3/s maximum. Moreover, the TRCM will be equipped for removing floating debris in the vicinity of the trashracks, i.e. the TRCM will be able of removing floating debris at water levels as low as the MOL = 2412 m.a.s.l. The debris will be collected either with the bucket or with the grappling hook.

The TRCM will operate in manual and semi-automatic modes, controlled from the inside of the operator's cabin.

TRCM will include also a crane hook of adequate capacity for handling the intake stoplogs at the power intakes. The design and performance criteria of Trashracks and Trashracks cleaning machines are summarized in the following table:

Table 11-9 Trash racks & Trash rack Cleaning Machines

Trash racks		**Trash rack Cleaner**	
Type	Non withdrawal fixed type	Vertical Inclination	10 º

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

No. of trash racks	1 set	Rake “pay load”	1 ton
Handling	By mobile crane	-	-

11.15.5 Pressure Shaft

The lower, horizontal part of every pressure shaft will be steel lined, from the bifurcation onwards up to the spiral case inlets of the generating units.

For the feasibility design of the steel lining, safety factors of 2.0 and 1.5 were adopted to establish the required minimum plate thicknesses with regard to the prevailing internal and external pressures, respectively. Moreover, the steel lining was pre-dimensioned under the following assumptions:

- No load sharing with the surrounding rock, and
- Full external pressure with no pressure relief valves.

The material of the steel lining will be killed, fine grained steel with a yield strength of no less than 550 N/mm² for limiting the plate thickness so that no stress relieving after field welding is required.

11.15.6 Surge Shaft

Surge shaft is a structure provided at the end of pipe to account for water hammering effect in the pipe at its downstream. Surge shaft is considered to be an important component of power intake, especially for those involving headrace pressure tunnels.

When power house is suddenly shut down by closing the turbine valves the water in penstock stops suddenly and because of the inertia of incoming water from the back creates a resonance effect, which in a mean while causes water hammering effect. If no arrangement has been made to prevent this water hamming it may result in bursting of penstock pipe and may lead to serious stability issues of the hydropower project, the best solution is to provide a surge shat or surge tank depending upon the site constraints.

Design of Surge Shaft depends upon different parameters such as given below:

- Design discharge
- Headrace water level
- Headrace tunnel diameter
- Headrace tunnel length
- Headrace tunnel slope
- Headrace tunnel material

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Design discharge is the amount of water to be carried by the headrace tunnel of specific diameter with a pre-defined longitudinal slope, greater the slope more will be the velocity of water through headrace tunnel and hence more will be head losses.

11.15.7 Draft Tube Gate Equipment

11.15.7.1 Functional Requirements and General Arrangement

For installation, maintenance, inspection and repair of turbines, it is necessary to dewater the turbines and their related waterways. Draft tube gates are required to act as bulkheads for preventing entry of surge chamber water into the waterways when the turbines and their waterways are emptied for maintenance and inspection. Draft tube gates will work under balanced head conditions.

The draft tube gates will be vertical lift bulkhead type designed for operation under balanced head conditions created through filling valves installed on the gates.

Draft tube gate equipment will consist of bulkhead gates, lifting beam and overhead travelling crane.

11.15.7.2 Draft Tube Gates

Gate Leaf

The draft tube gates will have upstream side seals and downstream bottom sealing. Skin plate will be on downstream side. This concept of sealing and skin plate position is to prevent any uplift effect during surge tank operation. Each section will be of welded steel construction. The top section will have wedge type bottom seal and caisson type side and top seals with fluorocarbon cladding while the lower sections will have sealing plate at the top on which the upper section will be seated to seal the water passage. Guide shoes will be provided at the top and bottom of each side of the gate sections to engage the guides embedded in the concrete. For alignment of draft tube gate sections, guide pins will be installed on the top of lower sections and guide sleeves in the bottom of upper sections. Lifting pins will be provided to handle the gate sections by a lifting beam.

Embedded Parts

A set of embedded parts will consist of a sill beam, a lintel beam, two side bearing plates, two guide rails for installation of draft tube gates along with two guide rails and bottom supports for storage of draft tube gate sections. Welding pads will be embedded in first stage concrete to facilitate the alignment of the parts embedded in the second stage concrete. The sill and lintel beams will provide sealing surfaces for bottom and top sections of the gates respectively. All sealing surfaces will be of corrosion resisting steel. The design and performance criteria of graft tube gates are summarized in the following table:

Table 11-10 Design and Performance Criteria of Draft Tube Gates

Type of gate	Vertical Lift Gate
No. of gate openings	3
No. of draft tube gates	4

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

No. of embedded parts	3 sets
Gate operation	Overhead Travelling Crane

Overhead Travelling Crane

One electrically operated overhead travelling crane will be provided for handling the draft tube gates and inlet stoplogs of tailrace tunnels with the help of lifting beams. The lifting beams will operate in the slots and guide rails provided for the draft tube gates and inlet stoplogs for tailrace tunnels. The crane will operate over the rails spanning all the draft tubes of the powerhouse.

11.16 MECHANICAL COST ESTIMATION

It is assumed that a major portion of the mechanical equipment will be imported from foreign sources. The prices include profit, overheads and the cost of designing, purchasing raw materials, manufacturing, painting, testing and packing the products, delivering to the port of export, ocean freight, insurance, landing cost, inland transportation in Pakistan and installation. A contingency amount of 2% of the total costs of all mechanical equipment has been added to cover the additional costs arising from increases in equipment dimensions due to unforeseen physical conditions at site. Unforeseen site conditions have the greatest impact on civil works, but they can also impact, to a lesser extent, on the dimensions and cost of mechanical equipment

.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12 ELECTRICAL EQUIPMENT

12.1 GENERAL

This chapter is aimed to summarizing the feasibility design considerations for the electrical equipment and its installation in the powerhouse. The study shall provide the basis for the cost estimates and will form the background for the final design studies.

The main electric installation would consist of 03 nos. vertical shaft synchronous generators, 02 nos. GCBs and 03 nos. three-phase step-up power transformers. Medium Voltage, Low Voltage, DC Auxiliary power supply system and safety installations will provide adequate operational and personal safety.

Three power generating units having a total capacity of 54 MW with a generation voltage of 11kV will be located in the power house. The generators shall be connected to their respective unit transformers (three phase) through GCB to step-up the generation voltage for onwards transmission to the local grid. A GPS Clock synchronized time system for the common time basis of all the equipment, Lighting & small power services will be provided in the Power house along with earthing. All equipment shall operate without undue vibration and with the least practical amount of noise.

All equipment shall be designed to minimize corona or other electrical discharges, to comply with local electromagnetic compatibility (EMC) standards and IEC 60801 and IEC 61000.

All electrical components shall be adequately rated for their most onerous duty and the specified ambient temperature. When equipment is mounted in panels, cubicles etc., due account shall be taken of any heat generated by the equipment therein and the components shall be appropriately selected, rated or de-rated as necessary to suit the most onerous operating temperatures within the enclosure.

12.2 STANDARDS AND REGULATIONS

The works will comply with the relevant statutory requirements of Pakistan and WAPDA. The design, materials, manufacturing, testing, inspection and performance of the works will conform to the latest current ISO/IEC publications.

- IEC 60034 Rotating electrical machines
- IEC 60085 Thermal evaluation and classification of electrical insulation
- IP 44 Degree of protection

Other recognized national or international standards and codes that ensure substantial equivalent may be acceptable. For applications where no relevant standard exists, up-to date recognized practice will apply.

12.3 GENERATOR

All three generators shall be installed vertically & their rotors shall be solidly coupled with the turbine runner hydraulic driven with a combined thrust and guide bearings below the rotor upper

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

guide bearing neutral grounding assembly. Automatic Voltage regulators, excitation cubicles and a closed circuit cooling system surface air cooler shall be installed. A flywheel of suitable inertia will also be mounted on the same shaft to keep the constant speed of the generator & avoiding the fluctuations/harmonics resulting from varying loads and switching surges. All the Generator parts shall safely withstand stresses resulting from over speed conditions at runaway. Generator terminals are connected by Isolated Phase Bus ducts (IPBs) to Generator Circuit Breaker (GCB).

Each generator shall be provided with a set of brakes arranged for pneumatic operation from station compressed air system. A rotor maintenance jacking system will be supplied to lift the turbine and generator rotating parts.

Each generator shall have a closed circuit air-cooling system in which the circulation of the air is achieved by the fan action of the rotor. The air leaving the generator will be cooled by a number of surface type air/water coolers. With one complete heat exchanger out of service, the maximum continuous output will be maintained without the stator and rotor winding temperatures exceeding Class B permissible temperature rise. Electric heaters shall be provided in all generator housing to prevent condensation when the generator is not working. The lower bearing bracket shall support the weight of the rotating parts and the hydraulic thrust of the turbine. The bearing arrangement shall be according to IEC60034-7. Stator and rotor insulation shall be rated for class F; however, the temperature rise of the stator and rotor windings shall not exceed the Class B limits specified in IEC 60034-1.

12.3.1 Type & Description

The three-phase synchronous generators shall be of the vertical shaft type, hydraulic driven, with a combined thrust and guide bearing below the rotor, upper guide bearing, neutral grounding assembly, CO_2 fire extinguishing system and a closed system of ventilation with surface air coolers. Generator terminals will be connected by Isolated Phase Bus ducts (IPBs) to Generator Circuit Breaker (GCB).

The Generator shall be suitable for direct connection to a Francis type vertical shaft turbine. The direction of rotation of the turbines will be clockwise when viewed from non-driven end. The stator bore shall be such that it allows lifting the largest turbine component through it. The neutral grounding of the generators shall be through a dry-type distribution transformer connected between the neutral of the generator and earth with resistor connected at the secondary winding.

The generators shall be designed to withstand all fault situations that can be experienced during operation without any displacement of its windings or mechanical damage to any of its parts or to the generator foundations, such as short circuit between two or three phases at its terminals, faulty synchronization, magnetic imbalance due to pole winding failure and runaway conditions etc.

The generator condition monitoring system shall comprise the following features:

- On-line Vibration Monitoring System
- On-line Partial Discharge (PD) Monitoring System
- Generator Air Gap Monitoring System

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 12-1 Main Parameters of the Generators

Generator Shaft Orientation	Vertically Coupled
No. of Units	3
Nominal Capacity	21.2 MVA (18 MW)
Rated Speed	375 RPM
No. of Poles	16
Efficiency	98 %
Unit Output Voltage	11 kV
Frequency	50 Hz
Power Factor	0.85
Insulation Class	F
Limit of Thermal Utilization	B
Excitation	Static
Excitation Voltage	220 V DC
Runway speed	648 rpm
Connection	Y, Neutral Grounded through transformer resistance
Cooling System	Closed circuit Air-cooling system with surface type Air/Water Coolers

12.3.2 Design

The generator shall be of a standard construction according to the respective IEC-60034 standard. The design of the generator is determined by the construction, layout and speed of the turbine. The choice of a vertical shaft Francis turbine with 375 rpm defines a vertical generator with 16 poles with upper guide and thrust bearing and lower guide bearing. The design of the frame and the foundation will have to carry the weight of the turbine and the generator as well as to take over the stresses caused by the dynamic forces produced during short circuit conditions on the generator side as well as the stresses caused by seismic activities. CO2 fire extinguishing system and a closed system of ventilation with surface air coolers. Generator terminals are connected by Isolated Phase Bus ducts (IPBs) to Generator Circuit Breaker (GCB). The nominal voltage of the generator has been chosen 11 kV which is appropriate for this size of the Generators and standard WAPDA system. The generators are capable to run at 15% continuous overload without exceeding the temperature limits of class F insulation.

The generator is designed to withstand all fault situations that can be experienced during operation without any displacement of its windings or mechanical damage to any of its parts or to the generator foundations, such as short circuit between two or three phases at its terminals, faulty synchronization, magnetic imbalance due to pole winding failure and runaway conditions etc.

The power factor of the machines is proposed to be 0.90. The generator shall meet the specified temperature rise limits, based on an ambient temperature not exceeding 40C. The voltages withstand levels for the generator shall be in accordance with IEC 60071.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12.3.3 Rotor

The rotor structure supporting the pole pieces built up of steel laminations shall be of steel plates or with a central cast steel/fabricated spider, equipped with field windings as well as with collector rings. The poles shall be laminated and provided with a damper winding for the required operating stability. Any method of securing the poles to the rotor body shall depend on the stressing by the centrifugal force that is developed at the runaway speed. The poles shall be fully consolidated laminated assemblies fitted to the rim. The pole fixing shall be designed so as to limit stress concentrations, and ensure uniform load distribution between fixings.

The insulation class of the pole windings has to be "F" but for extended insulation life the generators would be rated at class "B" temperature rises. Damper bars of copper shall be braced into ring segments at both ends of the rotor. The rotor is provided with a continuous low resistance damper winding in the pole pieces to minimize over voltages due to unbalanced faults. The damper winding is designed to make the ratio of quadrature-axis sub-transient reactance (xq'') to direct-axis sub-transient reactance (xd'') nearly equal to 1.0 for stabilizing the power system transient swing.

A segmental brake ring shall be fitted to the rotor with provision for expansion and contraction due to repetitive normal braking. The design shall be such that the brake ring segments can be readily removed for resurfacing or replacement. The brake ring shall be sufficiently thick to prevent thermal distortion. It shall comprise bolted segments which shall present a smooth even surface to the brake pads. Bolts shall be well countersunk.

The Generators shall be efficiently cooled with closed air system. For proper cooling, the Generators shall be equipped with surface air water coolers having sufficient cooling capacity to maintain the air temperature at 40˚C or less, with the generator delivering continuously 100% rated output. The circulation of the air shall be by means of the fan action of the Generator rotor.

12.3.4 Stator

The stator should be framed by welded steel rings on both sides, which transmit all dynamic and static forces through thrust bearing to the plates laid in the concrete foundations. Stator bars shall be treated with anti-corona protection and wound in the slot with conducting materials designed to compensate for relaxation in service, in order to eliminate the possibility of slot discharge damage. Stator wedges shall be fitted in such a way that radial pressure is applied to the bars even after relaxation in service. The interval between wedge re-tightening, and the method adopted, shall be subject to the Engineer's approval. Stator bar joints shall be brazed, and bar to bar joints fully insulated with tape material.

For proper and effective cooling the generator core shall be divided by radial and axial air gaps for air flow through the generator core. The stator winding shall be designed so that a generator wave form as close as possible to the sine curve could be obtained. The stator winding is star connected and neutral point is grounded through a grounding transformer. The stator winding is provided with an online partial discharge measuring system with necessary partial discharge sensors to measure the partial discharge activities in such various plates of stator windings as external to the stator winding, slot surface, slot wall, insulation/copper interface and end turn

The stator winding shall be made of bar or coil winding system with an insulation of continuous tape impregnated with synthetic resin in vacuum and subsequently cured. The coil shall be provided with a necessary anti corona protection in the slot section and at the ends, if

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

necessary. The insulation shall meet the requirements of the temperature class F. Grounding of generator neutral through grounding transformer is proposed. The Grounding resistors shall be installed in a separate housing with proper insulation provided.

The winding shall be designed to minimize temperature variation throughout the slot content. Bars shall be manufactured and wound to an agreed quality plan which shall be approved by the Engineer.

Stator bars shall be treated with anti-corona protection and wound in the slot with conducting materials designed to compensate for relaxation in service, in order to eliminate the possibility of slot discharge damage. Stator wedges shall be fitted in such a way that radial pressure is applied to the bars even after relaxation in service.

The interval between wedge re-tightening, and the method adopted, shall be subject to the Engineer's approval. Stator bar joints shall be brazed, and bar to bar joints fully insulated with tape material.

Windings shall be braced and supported so that they can withstand short circuit forces and accommodate thermal cycle movement without damage. Slot wedges shall be locked in position so that they cannot fall out of the slot. Bars shall be fixed, using conformable packing, to insulated non- metallic support rings. All bar clamping devices shall be locked by approved means. The method of winding support and wedging shall be shown in the drawings to be submitted by the Contractor.

Stator bar joint and connecting ring maximum temperature rises shall not exceed those allowed in the slot portion of the winding. The predicted maximum temperature rises, shall be validated by tests.

Air gap measuring probes shall be fitted in the slot wedges to monitor abnormal air gap changes. The probes shall be connected to a processor mounted outside the machine enclosure. The proposed system shall be complete with interface equipment to provide signals to the Distributed Control system (DCS) for alarm purposes and for deterioration analysis, required to plan preventative maintenance.

Suitable connections shall be installed in each phase of the winding to monitor "on line" discharge levels of the bars, without taking the unit out of service.

12.3.5 Generator Bearings

Guide bearings shall be of the segmented multiple pad design, oil lubricated self-pumping type. Their design shall permit vertical movement of the shaft system for adjustment and removal of the thrust bearing shoes. Bearing pads shall be individually adjustable and shall be lined with high grade white metal, no less than 5mm thick, securely bonded to the pads. The bond shall be ultrasonically examined. Bearing pads shall be easily removable without the removal of any other major component. A portion of the bearing shall be continually immersed in oil to provide initial lubrication during a unit start.

All bearings shall be equipped with water-in-oil sensors with alarms. Each generator bearing housing shall be sealed and ventilated to ensure that oil vapor does not enter the generator, slip-ring housing or turbine pit. Vapor pipe work from each bearing housing shall be terminated in a convenient location in the turbine gallery, by condensate containers equipped with drain

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

and level indicator. If necessary to completely eliminate vapor release from the bearing housings, an external vapor extraction and condensation system shall be provided for each unit.

12.3.5.1 Generator Lower Guide Bearing

The lower guide bearing may share an oil reservoir with the thrust bearing. In this case oil supply to the lower guide bearing may be by the pumping action of the thrust bearing. Otherwise the guide bearing shall be self-pumping.

If a separate oil reservoir is used, the coolers of the lower generator guide bearing shall be external to the guide bearing housing and shall be easily isolated and removable for cleaning and maintenance.

Alternatively, if self-pumping is proven to be impractical with external coolers then coolers may be installed in flanged recesses in the bearing houses such that they can be removed without the necessity of dismantling any major component.

12.3.5.2 Generator Upper Guide Bearing

The bearing shall be of self-pumping design mounted in the upper bracket. Coolers shall be consistent with those on the lower guide. It shall be possible to remove the upper guide bearing pads without dismantling the brush gear or its enclosure.

12.3.5.3 Generator Thrust Bearing

The thrust bearing shall be self-pumping by rotation of the shaft. It shall be mounted in a lower bracket designed to transmit axial loads into the concrete foundations. The design shall be such as to limit thermal expansion forces whilst maintaining the bearing concentricity with the shaft. The thrust pads shall be supported so as to ensure uniform load distribution between pads and provide ease of adjustment for maintenance. The bearing shall be designed to accommodate repetitive restarts immediately after hot shut down. Removal of the pads shall be possible sideways by jacking the generator rotor. The Contractor shall supply all special tools and devices for this purpose.

The thrust bearing runner shall be a one-piece forging. Weld repair of the runner surface will not be accepted. The bond of the white metal to the bearing pads shall be inspected ultrasonically.

The thrust bearing shall be equipped with a high pressure oil lift system which shall normally be operative during start up and shut down. However, it shall be possible (and demonstrated during commissioning) that the unit can be stopped without the pumps in operation without any appreciable temperature rise and any damage to thrust bearing pads. The results of this demonstration shall be visually verified by inspecting two thrust bearing pads at random. Each pad shall be equipped with non-return valve integral with the pad. The high pressure system shall comprise two pumps (normal and standby) with all necessary starters and associated controls for automatic switching. The standby pump shall be dc motor driven which shall start automatically upon failure of ac motor driven main pump. The required oil film thickness shall be established in about five (5) seconds. Remote indication and local visual indication shall be provided for excess inlet and outlet filter pressure drop.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The high pressure lift system shall be located external to the unit so that it can be easily inspected and maintained without entering the unit. Automatic drainage of any leakage oil shall be provided. Bearing oil coolers shall be mounted outside the bearing housings with isolating valves so that they can be removed for cleaning. There shall be indicating devices or visual aids to observe foaming of oil in the bearing.

12.3.6 Condition Monitoring System

The generator condition monitoring system will comprise of the following features

On-line Vibration Monitoring System

The generators are provided with a vibration measuring system to monitor vibrations of radial and axial directions as well as shaft run-out at each bearing of the turbine and generator unit. The vibration measuring system is arranged to measure the following items.

a) At upper guide bearing: Vibrations of radial (X and Y) directions
   Shaft runout of radial (X and Y) directions
b) At thrust bearing: Vibrations of axial direction
c) At lower guide bearing: Vibrations of radial (X and Y) directions
   Shaft runout of radial (X and Y) directions
d) At turbine guide bearing Vibrations of radial (X and Y) directions
   Shaft runout of radial (X and Y) directions

The vibration indication units are mounted on the turbine control panel.

The vibration measuring system is designed to give alarm (1st stage) and unit trip (2nd stage) signals in the event of excessive vibration.

On-line Partial Discharge (PD) Monitoring System

In order to indicate the condition of winding insulation, a partial discharge analyzer (PDA) is provided to monitor the partial discharge activities of the stator windings. The system consists of permanently mounted partial discharge sensors (capacitive couplers) on the line and neutral windings.

Generator Air Gap Monitoring System

Air gap monitoring system consists of stator mounted probes to detect the deformation of rotor and stator concentricity. Data will be used for analysis of irregular behavior of rotor and stator due to effects of centrifugal force, magnetic force and thermal expansion on generator.

12.3.7 Excitation System

The generator excitation system will be of the static type comprising three-phase cast resin type excitation transformer, thyristor converter, field flashing and field discharge equipment, automatic voltage regulator and control circuitry. The excitation transformer will be installed in a

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

self-supported steel plate cubicle to achieve personnel safety. The excitation transformer shall be AN cooled and of dry insulated type using non-flammable Class B insulating material.

Static excitation with excitation transformer, controlled rectifier and the automatic voltage controller has the advantage of providing quick response, being capable of reversing its output voltage in case of load rejection and unit over speed. Therefore, the proposed Power House shall have a static excitation system.

Excitation systems feed the field winding via slip rings and brushes allowing rapid response for voltage regulation. The automatic voltage regulator will be equipped with automatic and manual channels with follow-up control to allow change of mode without bumping. The excitation rectifier envisaged will be of solid-state type with controlled silicon power thyristor for both polarities. While considering forced ventilation, redundancy of the cooling system must be provided to avoid shutdown of the generator in the event of breakdown of the fan motors. Cooling fans must be self-powered from the excitation transformer so that loss of station service does not cause excitation failures.

The excitation system will be capable of providing sufficient margin of stability under all steady and transient load conditions. The voltage regulator will have a voltage variation range of ± 10 % of the rated generator voltage. The field current control will be used as the manual channel of the regulator. The excitation system shall have built-in protection and supervision equipment. All fault signals shall be displayed on the AVR front panel.

For excitation start-up / field flashing, an additional supply from the DC system will be provided. The excitation system will communicate with the distributed control system (DCS) via a standard bus system.

The static excitation systems will consist of:

- Digital type AVR’s
- Rectifier assemblies
- Excitation transformers
- Field cubicles with breakers, discharge, control & protection devices and cooling circuits
- Field flashing circuit/equipment
- Excitation leads between excitation cubicles and slip rings

The excitation system will be provided with the following features:

- Following of line voltage during synchronization
- Quadrature droop parallel operation compensation
- Under-excitation or load angle limitation with adjusting device
- Time graded limitation of the maximum excitation current

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Time graded limitation of the maximum stator currents (under-/ overexcited)
- Power system stabilizer

12.3.8 Generator Circuit Breaker

The Generator Circuit Breakers will be SF6 gas type as insulating and interrupting medium, high current type and complying with IEEE C37.013. For current interruption the self-blast interrupting principle is applied. The arc voltage of the circuit breaker is high enough to ensure current zeros in case of generator-source short-circuit currents with delayed current zeros. The Generator Circuit Breakers will be suitable for synchronizing duties and provided with interlocks to avoid incorrect operation of the disconnector or the earth switches. The Generator Circuit Breaker is capable of interrupting currents under out-of-phase conditions with out-of-phase angles up to 180 degrees.

The Generator Circuit Breakers will conform to IEC 60694 and suitable for the normal load current specified with natural cooling and with a temperature rise in accordance with IEEE C37.013.

12.4 OTHER ELECTRICAL EQUIPMENT

Generator protection comprising all the required relays according to the size and specifications of generator.

- Control and metering panels.
- Control and protection cables.
- MV/LV switchgears.
- 220V DC Battery Set & Battery Charger.
- Energy Hour Meters shall be used to monitor energy generation.

12.5 POWER TRANSFORMERS

Power transformers configuration have been considered to transmit the power from power house to local grid station.

Each generator connected to its own unit transformer.

It has advantages of being flexible in case of problems with the equipment. Each unit is independent so that availability of the generation is higher than the group transformer. Thus for this hydropower project, each generator is proposed to connect to its own step-up transformer. Off load tap changer is proposed on high voltage side. An allowance of 10% continuous over load is also proposed. Detailed parameters of the recommended transformer are as under:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 12-2 Recommended parameters of the Transformers

Description	For Generator I to III
No. of Transformers	03
Nominal Capacity	22 MVA
Cooling Type	ONAN/ONAF
% Impedance	12%
Primary Voltage	11 KV
Secondary Voltage	132 KV
Frequency	50 Hz
Type	3-Phase, 2 windings (HV/LV)
Tap Changer	OFF Load
Vector Group	Ynd11

A spare power transformer shall also be provided. As per standard practice, Buchholz Protection and all other necessary Protection will be provided. The delta connected winding on the low voltage side will provide short-circuit for possible third harmonics from the generator. The high voltage winding is star (Y) connected with the neutral taken out on a separate terminal for connection to earth.

12.6 STATION SERVICE TRANSFORMER

One transformers of 2 MVA, 132/11 KV rating will be installed for power supply to intake, auxiliary supply, control room, transformer bay, intake, crane, Lighting Load, DC supply and power house supply and as alternative supply in case of emergency.

The ratings of transformer are as under:

No. of Transformer	1
Capacity	2 MVA
Primary Voltage	132 kV
Secondary Voltage	11 KV
Frequency	50 Hz
Temperature rise	55˚C
Cooling	ONAN
Type	Dry/Oil

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12.7 AUXILIARY TRANSFORMERS

Two nos. Unit Auxiliary Transformers (UAT's) will be installed for power house auxiliary supply. It is not necessary to install a unit auxiliary transformer with each unit. Here, It is considered economical to install 11/0.4 kV transformer only with two units. Another unit auxiliary transformer will be used to interconnect unit auxiliary supply with station supply to get the supply from station service transformer. The ratings of unit auxiliary transformers are mentioned below.

No. of transformers	3
Rated Capacity	630 kVA
Transformation voltage	11 kV / 0.4 KV
Insulation class	H
Cooling	ONAN
Type	Oil
Percentage Impedance	4 %

Two auxiliary transformers of capacity 400 kVA each shall supply the electrical power to the auxiliary equipment of intake and switch- yard control building. Oil filled distribution type transformer with a capacity of 400 KVA, 11KV/0.4kV, has been selected based on the required capacity of load in the plant. Natural air circulation cooling has been chosen due to the operational safety. The insulation material shall be self-extinguishing and varnish shall prevent any spreading of fire. The units shall be installed close to the space where the power is needed. The ratings and characteristics of the auxiliary transformer shall be as follows.

No. of transformers	2
Rated Capacity	400 kVA
Transformation voltage	11 kV / 0.4 KV
Insulation class	H
Cooling	ONAN
Type	Oil
Percentage Impedance	4 %

12.8 SWITCHGEAR SYSTEM

The generators shall be connected to 11kV switch gear, which consists of medium voltage circuit breakers, medium voltage disconnecting switches and the corresponding metering and protection equipment.

12.8.1 132kV Switchgear

Conventional air insulated type switchgear is applied for 132 kV switchyard for connection of the outgoing 132kV transmission line which includes voltage and current transformers for protection relays.

132kV switchgear is figured with one and a half circuit breakers system being generally applied for high voltage system in substation and power house.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12.8.2 11kV Switchgear

The primary purpose of the 11 kV switchgear is to provide auxiliary supply for the powerhouse, intake and also to support any adjoining areas. The switchgear has been planned to be located in a separate room in the 132kV switchyard.

The incoming 11 kV supply from 132/11 kV service supply transformer will be terminated in the 11 kV bus bar. Some 11kV feeders supply power to rural areas and will be finalized in the tender design stage.

The necessary 11 kV feeders and service supply transformer will be equipped with modern fuse disconnecting switches or circuit breaker of SF6 or vacuum type (to be decided at detailed design stage) enclosed in cubicles thus obtaining high personnel safety.

The main data for the circuit breaker shall be the following:

Nominal voltage	11 kV
Maximum voltage	12 kV
BIL	95 kV
Rated short circuit current	31.5 kA

12.8.3 400 Volt Switchgear

It is proposed to use a 400V switchgear scheme to supply power to station auxiliaries. The AC supply of 400V shall be obtained from the 630 KVA station service transformers. Miniature Circuit Breaker and Molded Case Circuit Breaker (MCB's & MCCB's) shall be used accordingly for the 400V supply.

The following LV switchgears are provided for Unit and Station Auxiliary power supply.

a) Unit Auxiliary service boards

b) Essential service boards

c) Common service boards

Switchgear assemblies will be comprised of low voltage power air circuit breakers, moulded case circuit breakers, buses, current transformers, voltage transformers, indicating instruments, relays, control devices, associated wiring and test blocks.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12.9 CONTROL, INSTRUMENTATION AND PROTECTION EQUIPMENT

12.9.1 Instrumentation & Control

1) One-Man Control System

The control system for each generating unit; hydraulic turbine, generator, unit transformer and 132kV circuit breaker will be designed for “one-man control system” in which any operation of the generating unit can be carried out remotely by an operator from the machine hall in the powerhouse as well as from the main control room of the central control building.

In the one-man control system, the unit start-up and stop operations will be made by automatic sequential control with the aid of the programmable logic controller for each unit. All auxiliary equipment of the unit will be actuated and stopped by automatic control sequence program loaded in the PLC.

2) Control Mode

Each generating unit will be operated under three (3) control modes of "Remote- Auto", "Local-Auto" or “Local-Manual” as follows:

a) Remote-Auto” Control Mode

The generating unit operation including unit start/stop, turbine speed adjustment, load adjustment and generator voltage adjustment will be carried out remotely from the control room of the main control building.

The unit start/stop operations will be carried out under the full-automatic mode. The remote-auto control mode will be used for ordinary start and stop operation.

a) Local-Auto” control mode

The generating unit operation will be carried out remotely from the machine hall floor level of the underground powerhouse.

Under the local-auto control mode, the unit start/stop operations will be made by full-automatic mode or step-by-step mode.

Under the full-automatic mode, the generating unit will start up automatically to the step of the generator synchronizing when the “Start” command is given, and the running unit will be automatically brought to the unit standstill when the “Stop” command is given.

The step-by-step mode is a semi-automatic control mode to start and stop the generating unit from the unit local control board with confirmation of each step operation. This local-auto control mode will be used when the SCADA system is out of service.

b) Local-Manual” Control Mode

The local-manual control mode is to operate the turbine and generator unit by manual control of their governor, excitation system and auxiliary equipment without using the automatic control function of the programmable logic controller.

This mode will be used only for testing and trial operation of the turbine and generator unit after maintenance and repair, or when the programmable logic controller is out of service.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Indicating, measuring and control instruments have been considered necessary for the major components of Power House. For monitoring and control of the overall power plant, Latest control system (DCS/SCADA) should be installed for plant control. The transducers shall be installed where necessary. All indications shall be visible in the main control room.

The control of the single unit shall be local and remote, able for auto or manual selection. It is necessary to provide a separate control desk and mimic panel that shall be located in the main control room and include the most important remote control functions.

12.9.2 Protection Equipment

Separate relay protection cubicles comprising modern electronic relays will be installed. All relays shall preferably be of the same make (manufacture) to build a uniform modular system.

The relays are to be organized in two groups so that one group provides back-up protection for the other group The outline of protection scheme for the Generators, Main Step-Up Transformers, is shown on the Design Drawing. The general principle for the protection is that all parts of the installation (Generator and Main Step-Up Transformers) are covered by two high speed protection schemes which are independent to avoid common-mode failures.

The protection equipment is provided with all relay panels, instruments, meters, interposing and auxiliary relays, control switches, interposing current and voltage transformers, transducers and all auxiliary equipment. The protection system aims at compliance with IEC 62351. Control supply will be taken from 220 VDC system. Separate circuits will serve the two groups of relays in order to obtain maximum reliability. Protection equipment is designed and supplied to provide maximum discrimination between faulty and healthy circuits. All equipment is to remain inoperative during transient phenomena which may arise during switching or other disturbances to the system.

Signals and data provided by the protection relays will be monitored by the DCS.

12.9.2.1 Generator Protection

- Under voltage protection (27)
- Reverse power protection (32)
- Loss of excitation protection (40)
- Negative sequence current protection (46)
- Generator winding thermal monitoring (49 G)
- Over current / short circuit protection (50; 51; 51 N)
- Over voltage protection (59)
- Rotor earth fault protection (64 R)
- Stator earth fault protection (95 % & 100%) (64 G)
- Under frequency protection (81)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Three phase generator differential current protection (87 G)
- Shaft current protection
- Vibration and shaft movement supervision protection

12.9.2.2 Power Transformer Protection

The following transformer protections are recommended:

- Transformer Differential protection
- Restricted earth fault protection
- Back-up earth fault protection
- Buchholz protection
- 132 kV XLPE cable differential protection

And also over current protection for excitation transformer and unit auxiliary transformers will be provided.

It is also recommended that the numerical transformer protection system be combined with the main generator protection system and contained in one cubicle or in an adjacent cubicle.

The following devices, supplied as part of the unit transformer shall be integrated in the transformer protection and supervision scheme.

- Level of insulating oil, maximum and minimum (71T);
- Oil temperature (26);
- High voltage (HV) and low voltage (LV) windings temperature (49T);
- Gas release (63);
- Pressure relief valve (63VS)

12.9.2.3 132kV Transmission Line Protection

The 132kV transmission line protection shall be comprised by redundant multifunctional numeric IEDs, with exclusive hardware.

- Transmission line differential protection (87L)
- Transmission line distance protection (21)
- Breaker failure protection (50BF)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12.10 SYNCHRONIZING

12.10.1 Automatic Synchronizer

A solid-state automatic synchronizer for each unit, to automatically synchronize and connect the generators to the power system via the unit 132 kV circuit-breakers will be provided.

I. The automatic synchronizing equipment will be mounted on the unit control panel.

II. A check synchronizing relay for each unit, which will be arranged to prevent closing pulses from the auto-synchronizer reaching the circuit breaker if the phase angle difference at that time is greater than nominal 5 degrees will be provided. Operation of the auto -synchronizer circuit breaker closing pulse without the check synchronizing relay operating will lockout the auto-synchronizer and initiate an urgent alarm.

12.10.2 Manual Synchronizing Facilities

A manual synchronizing for each turbine generator unit in the power station control room will be provided.

All hardwired voltage and speed control signals of the Project Plant units on the above console, to enable the operators to adjust the voltage and speed of the unit during manual synchronizing, will be provided.

12.11 MEASURING EQUIPMENT

Each feeder will be equipped with current and voltage transformers between the power transformer and the circuit breaker. Measuring accuracy of the protection cores shall be as per IEC standard. CT's shall be designed to carry the same nominal and short circuit currents as the other switchgear equipment and shall have separate cores for measuring and protection purposes. All measuring transformers are assumed to be dimensioned to meet all the needs of the operation of the power plant.

12.11.1 Current Transformers (CT)

Current transformers shall comply with IEC 61869-2 as amended and supplemented by the following requirements. Separate current transformers shall be provided for protection, instrumentation and metering purposes. For measuring current transformers, the following accuracy classes shall apply;

a) For generator output for the purposes of acceptance testing, and for tariff metering of large supplies, unless otherwise specified

b) For plant record metering, and for other acceptance testing purposes

c) For automatic voltage regulators (AVRs)

d) For indicating instruments.

Current transformers used for indication/metering purposes shall be designed to saturate at a value of primary current sufficiently low enough to protect the secondary circuit from damage at all possible values of primary fault current up to the associated primary short time rating.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Current transformers for protective/indication purposes shall be designed to suit the particular requirements of the associated protection which, in general, shall be in accordance with the recommendation given in IEC 61869-2. Class 5P current transformers shall be used for combined over current and earth fault protection of the inverse time over current type.

The rated accuracy limit with actual burden connected shall be equivalent to the ultimate maximum symmetrical three phase fault current or earth fault current of the protected circuit. The current transformers shall be capable of meeting the 5P error classification at rated accuracy limit current over the full range of relay settings.

Current transformers for combined purposes e.g. inverse time relays and indicating meters, shall have a dual Class 5P/Class 1 performance and where necessary the secondary circuits shall have an approved means of protecting the meters and reducing their burden under system fault conditions. Current transformers for protection using high impedance relays shall be of the low reactance type and their performance shall be stated in terms of the Class TPS, TPX, TPY and TPZ parameters of IEC 61869-2 (low reactance current transformers are preferred for all forms of protection), or equivalent approved standard.

The rated volt-amp output of each current transformer shall not be less than the connected burden, as installed in service, the burden of cable connections being taken into account. Current transformers shall be capable of withstanding without damage the peak and rated short time currents of their associated equipment. The secondary windings of each set of current transformers shall be earthed at one point only, via a bolted disconnecting link.

The current transformer core, where accessible, shall be separately earthed. When multiple ratio secondary windings are specified, a label shall be provided at the secondary terminals of the current transformer, indicating clearly the connections required for each tap. The connections and the ratio in use shall be indicated on all connection diagrams. Design magnetization curves and DC resistance values shall be submitted before manufacture for each current transformer used for protective purposes and shall be subsequently verified by works routine tests. For metal-clad switchgear, all current transformers shall be located on the outgoing circuit side of the circuit breaker. Current transformers may also be provided on the bus bar side of the circuit breaker to permit protection zone overlap.

The primary conductors of all current transformers shall be readily accessible for primary injection testing on site. Where current transformers have to be mounted on apparatus provided under other contracts, shall be responsible for ensuring compatibility with the other apparatus. Current transformers incorporated in equipment which are spare or for future use, shall (if not connected to associated relays, instruments etc.) be provided with a suitably rated shorting link mounted at a convenient terminal block to avoid the current transformer being energized with its secondary connections open circuited. Bushing type current transformers shall be provided with taps to measure capacitance and loss factor (tan delta).

12.11.2 Voltage Transformers (VT)

All voltage transformers shall comply with the requirements of IEC 61869-3 as amended and supplemented by this specification. They shall have outputs 50% in excess of the present requirements unless otherwise specified.

The voltage transformer secondary circuits shall be complete in themselves and shall be earthed at one point only. Metal cases shall be separately earthed. The transformer core,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

where accessible, shall be separately earthed. All voltage transformers at the same voltage level shall be earthed in the same manner. Where it is required to earth the primary neutral of a metal clad voltage transformer, the neutral earthing connection shall be insulated from the tank and brought out separately from the secondary earthing connection. Primary windings shall be connected through fuses with current limiting resistances or having current limiting features. However, such fuses may be omitted when the voltage transformer is located within the overall protection zone of the main circuit. Secondary main protection fuses or miniature circuit breakers shall be provided as close as possible to, and preferably mounted on, each voltage transformer, within a lockable or bolted enclosure.

Secondary main protection fuses or miniature circuit breakers shall be labeled to show their function and phase color. It shall not be necessary to de-energize the primary circuit or remove the voltage transformer of metal clad switchgear to gain access to the fuses or miniature circuit breaker. Auxiliary contacts shall be provided for alarm purposes in the event of loss of supply. Voltage transformers shall be so designed that saturation of their cores does not occur when 1.732 times normal voltage is applied to each winding.

Magnetization curves shall be submitted for approval for each type of voltage transformer prior to Works Tests. The standard secondary voltage between phases shall be 110 V unless special circumstances dictate otherwise. Secondary circuits of different voltage transformers shall not be connected in parallel. Voltage transformers shall preferably be mounted on the outgoing circuit side of circuit breakers. Three phase voltage transformers having an earthed - star primary winding shall have cores with five limbs, the outer two of which shall be unwound

12.12 SURGE ARRESTERS

On the outgoing transmission line surge arrester (SA) will be connected to each phase. In addition, one group of three SA will be included on each transformer bushing.

Surge arrestors shall be gapless non-linear metal-oxide resistors (Zinc oxide surge arrestor). The magnitude and duration of temporary power frequency switching over voltages are important design criteria and are to be defined during the final design stage.

12.13 DC POWER SUPPLY

220V DC Power shall be obtained by rectifying the AC Power. The DC supply shall also be supplemented by a DC Battery Set. Purpose of the battery system is to provide a safe and reliable DC power to all primary functions. The system is almost independent of all other power supply systems and ensures reliable execution of the control functions, both for selected normal operation and during possible fault conditions.

The DC battery system will mainly provide power to the complete Plant Control System. Some instruments, protection devices or computer interfaces will need 24 V or 48 V DC supply. In this case AC/DC converters should be used. The use of separate 24 V or 48 V batteries is not recommended. The Ah capacity of batteries shall be finalized at the final design stage on the basis of the actual DC load requirements of each powerhouse.

12.14 CABLES

The insulating, sheathing and non-metallic filler materials used in the cables shall be selected to ensure compliance with statutory and Section 16 for flame retardant or fire resistance,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

reduced propagation or low emission of smoke, acid gas and halogens free for the cable as a whole. Cables installed on or connected to equipment that is subject to vibration, movement and/or expansion shall have stranded copper conductors throughout. These cables shall have crimped connectors for the termination of the conductors. Only conductors carrying signals of the same category shall be contained within any one multi core cable. To reduce the risk of common mode failure all cabling associated with high integrity signals, such as data transmission signals, signals from fiscal metering systems or with protection and/or safety systems shall be segregated from control cabling over the entire length of the cable run.

This segregation shall also apply to junction boxes and terminations. A further segregation is required to ensure that conductors forming part of intrinsically safe circuits are contained in cables reserved solely for such circuits. A minimum of 20 % spare capacity shall be included in all cables carrying either binary or analogue signals.

12.14.1 Power Cables

The power cables to be used between the generators, transformers and their respective 11 kV switchgears shall be XLPE as per IEC/WAPDA standards. Actual quantity/Length of the respective cables shall be decided at the final design. The insulation is of extruded chemically cross-linked polyethylene (XLPE) with sheath of LSHF and either of fire retardant or of fire resistance characteristics. The cables will be armoured and will contain semi-conducting screens and any tapes, binders, separators or bedding required to manufacture reliable, technically proven, high quality cable

12.14.2 Control Cables

Control cables are used for protection, instrumentation, control and communications. These shall be of stranded copper conductors or armored cables. These cables shall be standard product of a reputed manufacturer with a proven track record. The construction of the cables will be in compliance with the specified requirements and the related IEC Standards. Control cables will be laid in perforated steel trays or at the bottom of concrete trenches. . The earthing and lightning protection system is designed in accordance with the IEC / IEEE standards. The cable trays shall be mounted on the floor underneath the local control area, to have short connections between the different control panels, distribution boards, equipment and other auxiliary installations.

12.14.3 Telecommunication Cables

The application of telecommunication type cables shall be restricted to voice and data communication purposes. These cables shall comprise multiple twisted pairs, triples or quads, with copper conductors, polyethylene or XLPE insulated, laid up and screened overall. Each pair/triple/quad may be individually screened, where required to minimize cross-talk or interference. Cables which are to be direct buried or installed in accessible areas without external mechanical protection shall be armoured, un-armoured cables shall have a braided screen. Minimum 20% spare capacity shall be included in all cables. The insulation of the cores shall be colour coded in accordance with an appropriate international standard. In addition, the colour , construction, marking, etc., of telephone cabling shall be subject to any requirements laid down by the local telephone company or authority. Telephone type cables laid in the ground alongside power cables shall be capable of withstanding induced voltages from the power cable.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12.14.4 Fiber Optics Cables

Fiber optic cable shall be made up cores sheathed in 125 µm cladding, coated and reinforced using strengthening fibers for protection against crushing forces and excessive tension during installation. All fiber optic cables shall comply with an appropriate international standard. The outer jacket shall be made of a flame retardant polymer. A loose tube with minimum strain configuration that provides protection from external forces shall be used in dry and indoor applications.

Specific measures shall be taken to protect the fibers from the ingress and propagation of moisture. The outer sheath shall be resistant to water and hydrocarbon contamination. Gel filled loose tubes shall not be used for vertical cable runs or in submerged applications. Tight buffered or ruggedized fiber optic cable type shall be used for long runs or where the cable is to be buried or submerged.

Each cladded core shall have two coatings, the first coat 250-900 µm plastic layer; the second coat 200-400 µm layer of waterproof acetate. Direct buried fiber optic cable shall be of a steel wire or steel tape armoured construction. Single-mode fiber optic cables shall be used when there is only one propagation mode (single wave length) or where there is a long transmission distance. The fiber optic cores shall be either 7.1 or 8.5 µm diameter.

The cable shall be suitable for transmission of laser light. The optical cable shall be of the single mode type equipped with at least 24 fibers and shall be suitable for direct burial underground. The fiber cladding diameter required is 125 micron, optimized for 1310 nm, but suitable for transmission at 1550 nm wavelength. Construction and type testing shall be in accordance with the appropriate international standard with a maximum cabled fiber attenuation not exceeding 0.4 dB/km at 1310 nm; and not exceeding 0.35 dB/km at 1550 nm Multi-mode fiber optic cables shall have a core diameter of 50, 62.5 or 100 µm, of all dielectric construction, with a graded index, suitable for use in the wavelength range 850 to 1300 nm. Construction and type testing shall be in accordance with the appropriate international standard. Multimode fibers shall be suitable for the transmission of infrared light produced by LEDs.

Simplex fiber optic cables consist of only one fiber link and should be used for applications that require only one-way data transfer. Simplex can be applied to both single and multi-mode type fiber optic cables. Preferably the fiber optic cable shall be installed in one length without joints, however where joints cannot be avoided shall complete all jointing as specified below. No intermediate joints are permitted in multimode fiber optic cable joints shall be housed in a weatherproof joint box. Joint boxes shall be provided with the cable.

The joint box shall be made of corrosion resistant aluminum alloy or similar material. The cover shall be provided with a long life neoprene gasket to provide a seal against moisture and dust in an ambient environment of 100% humidity and 55 ºC. The cable inlet shall be similarly sealed. If joint box locations will be exposed to the sun then sunshades are required and these shall be provided with the joint boxes. Intermediate cable joint boxes will be provided at approximately 2 km intervals, subject to the maximum fabrication/drumming requirements from the manufacturer. The joint box shall be placed in suitably accessible positions and be appropriately marked.

The fibers shall be spliced by fusion techniques for minimum signal loss. A heat shrink optical supporting sleeve with inner mechanical reinforcement shall protect the splice. Terminations at either end of the cable runs will be performed into patch panels using ceramic ST connectors supply the patch panels unless otherwise stated in the general technical requirements. A fan

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

out kit to protect each fiber strand in its own buffer sheath shall be used when terminating loose-tube cables. Patch cords shall be used between patch panels and equipment cabinets within buildings. Patch cords shall be performed, tight buffered, single or duplex fiber cables, 62.5/125 micron, multi-mode type, provided in standard lengths complete with factory-installed ceramic ST connectors and with sheathing suitable for internal building use.

All patch cords shall be supplied and installed. All patch cord runs between cabinets shall be mechanically protected in conduit or closed trunking provided and installed. The conduit or trunking shall contain only fiber optic cables and fit fiber optic patch panels for all fiber optic cables in their supply.

The supply shall include any cabinet or enclosure necessary for their installation or protection. Patch panels shall be provided with sufficient ports to terminate all fibers entering the respective building, with 20 % spare installed connectors. Connector type shall be ST. Sufficient room shall be allowed within the patch panel for adequate cable and fiber management, allowing for bend radius control. Independent patch panels and splice trays shall be provided. Smooth fiber and tube management shall be provided. After cable installation and splicing the completed fibers shall be inspected and tested using an Optical Time Domain Reflectometer (OTDR). The OTDR traces generated shall provide as-built evidence of the actual losses on the installed cables.

12.15 ILLUMINATION AND SMALL POWER

An adequate indoor and outdoor lighting with illumination levels in accordance with recognized standards will be provided. Inside the powerhouse, an emergency lighting system powered from the station battery must be installed. The system will operate the instant when the normal power supply fails.

AC lighting and small power socket outlets, for 230 V, shall be single-phase, connected between phase and neutral of the 400 V system.

12.15.1 Lighting/Illumination System

A complete LED lighting system, with the individual components being of approved type and constructed of best quality materials shall be supplied, installed and commissioned. The scope of supply shall comprise, but is not limited to the following:

- Indoor and outdoor lighting for all equipment, structures, roads and outdoor operation areas as required for the plant
- Lighting main distribution
- Lighting sub-distributions
- Lighting fixtures with LED luminaries
- Power socket outlets
- Portable LED lamps

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Cabling, wiring, conduit system for the low voltage wiring, convenient outlets, lighting fixtures and lighting panel boards and lighting switches as well as all required installation material

- Specified spare parts and special tools

The average illumination levels, as measured at a height of 0.8 m above floor (above ground level), at any location, shall be as follows (minimum levels):

Turbine /Generator Floor	300 lux
Mechanical Floor and Rooms	300 lux
Unit Transformers and Outdoor transformers	200 lux
Street lighting	20 lux
Oil and water storage tank areas	50 lux
Outdoor operating areas, intake / spillway area	150 lux
Accessible cable trenches with fixed covers	60 lux
Indoor transformer rooms, corridors, stair cases, basements 200lux locker rooms, store rooms, toilets, machine rooms	200 lux
Switchgear rooms, battery rooms, day rooms foreman's rooms, dispensary	360 lux
Workshops, offices	500 lux
Control rooms, Relay rooms	800 lux

An aging factor of 20% shall be taken into account and therefore the lighting intensities of the fittings must be achieved as a minimum during the acceptance tests.

Throughout the installation the lighting intensity at local measuring and control points and instruments panels shall be at least 200 Lux. Additionally, all local push button stations, control stations, control panels, instrument racks, hand operated equipment like valves, etc., shall – if required due to the low surrounding illumination levels – be lit separately by means of suitable LED luminaries, mounted on poles or at adjacent structures, so as to obtain at least 200 lux illumination level.

The systems include light fixtures operating at 230 VAC (line to neutral connected). The power source for the internal lighting shall be derived from the 400V lighting switchboard.

The machine hall will be provided on both long walls with a chain of fluorescent lamps which are used for normal access. During maintenance and repair jobs on a unit, additional portable lamps will be used where necessary. The control room will have intensity controlled illumination, so that it might be adapted to special situations. Special attention will be paid to avoid reflections on monitor screens.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Fluorescent light fittings are preferred everywhere indoor where they are feasible. High pressure sodium vapour lamps with built in control gear which are economical and long lasting will be installed outdoors. In order to reduce the number of equipment types and sizes which have to be stocked as spares, there must be standardization of both lamps and fittings. This will result in relatively few varieties.

The illumination level for the emergency lighting will be at least 10 Lux in the entire powerhouse area except control room and unit control panel area. The illumination level of 30 Lux will be specified in those areas.

Portable battery handsets will be made available for additional lighting during maintenance works, e.g. in case of AC failure. These will be located at various important places in the powerhouse, switchyard and intake structures.

Exit lights will be installed above doors, staircases and floors along the emergency exit ways and those will be powered by the uninterruptible power system in the event of failure of auxiliary power supply.

12.15.2 Emergency Lighting:

In normal operation, it will be directly powered from the 400 VAC essential switchboards. When plant auxiliary supply fails following will occur,

The first 60 seconds, energy supply will be taken over by the uninterruptible power supply system. After 60 seconds, the supply will be obtained from the emergency diesel generator unit (Emergency load switchgear is separated from normal supply).

Both systems will have a main concept, common distributed “on / off” switches. Emergency lighting will therefore not come on automatically in vacant rooms where the lights are off. However, special consideration will be paid to areas containing “escape routes”.

12.16 EMERGENCY DIESEL GENERATORS

One no. 200kVA diesel generator set shall be provided to feed essential station load in case of outage of generating units. This will be connected to Low voltage switchgear board at P/H and will supply power to essential auxiliaries of the units, required for restart of units, a 75kVA DG Set at intake for emergency gate operation and selected emergency lights. The diesel generator will be standard 400volts, 4 wires, 50Hz, Auto start type. The diesel generators shall be supplied with a local control panel which shall include all facilities for remote, auto start and control by the station control system (SCS) as well as facilities for manual starting and loading.

The diesel generator sets will be installed in a properly ventilated room, equipped with fire detection and firefighting arrangements.

12.17 ELECTRICAL WORKSHOP

The power plant will be provided with an electrical workshop. It shall be consisting of essential equipment to perform the day to day maintenance of electrical equipment. The necessary electrical T&P and testing equipment i.e. voltmeter, ammeter, ohmmeter, odometer, megger meter, etc. with whole range of special and standard tools necessary to perform all electrical as

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

well as the associated mechanical work for maintenance and repair of the power plant equipment shall be required in the workshop.

Sizes and technical data of equipment shall principally be maintained but may be adjusted to fit with vendor's standard production program. Sizes of wrenches and other relevant tools shall be supplied according to the metric system.

12.18 GROUNDING SYSTEM

Metallic parts of all the electrical equipment in or around the powerhouse shall be connected to the grounding system for safety of the personnel and equipment. It shall use stranded bare copper conductor in the concrete floor slabs. Ground rods shall be driven in soil surrounding the powerhouses. The number of electrodes shall be determined during the final design stage, keeping in view the soil resistivity and touch/step voltage. The grounding grid shall be capable to sustain without damage heavy currents during short-circuits for specified time. The Engineer/contractor during detailed design study shall carryout the necessary measurements to determine the ground and ground water resistivity to be used for the calculations and the design.

The actual cross-section of the earthing conductors will be defined in the earthing system calculation. All equipment associated with the plant including reinforcement steel and embedded steelwork will be bonded to the earthing electrodes by adequately dimensioned conductors. Surge arresters and transformer neutrals will be directly connected to the main earthing conductor and /or particular earthing rods.

12.19 SCADA AND TELECOM SYSTEM

12.19.1 Functional Overview

The SCADA and Telecommunication system shall comprise three sub-systems:

- An In-plant Instrumentation and Control system allowing monitoring and control of the plant (referred hereafter as the station) including generators, all auxiliaries, the associated switchgear, and 132 kV switchyard.
- An interface to the existing NTDC SCADA system at the National Power Control Center (NPCC) Islamabad enabling system dispatchers partial control of the Attabad Lake Hydropower Plant from Islamabad.
- A Telecommunication System for the distribution of voice and data within the Power Plant and for exchange of voice and data with NPCC Islamabad.

12.19.2 Station Instrumentation and Control (I&C) System

An in-plant I&C system shall be deployed for the monitoring and control of the power house and auxiliary systems, including:

- Control of generators including output power and ALFC.
- The monitoring of rotor vibration and air gap for generators.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- The monitoring and limited control of spillway gates, power intake flows, water levels, and their auxiliaries.

- The operation of 132 kV Circuit Breakers (in association with NPCC).

The plant instrumentation and control functions can be performed by either a hierarchical SCADA or a distributed control system (DCS). In view of the modularity and superior fault tolerance capabilities of the DCS the latter is proposed for the in-plant or station I&C system. The DCS shall comprise smart transducers and instruments installed across the plant. The controllers, transducers and associated field devices shall communicate over a plant wide LAN. Internet Protocol (IP) and other open standard protocols shall be deployed with built in diagnostics to monitor device health and predict problems thereby avoiding downtime. Field transducers shall communicative with the controllers over industry standard protocols. The station operational staff shall be provided with a Human machine interface (HMI) set up in the station control room for control and routine operation of the power plant.

12.19.3 Interface with Existing NTDC SCADA System

Selective key parameters of the Attabad Lake power complex shall be remotely monitored by NPCC and key functions will be remotely controlled from the National Power Control Centre (NPCC), Islamabad in line with NTDC's standard operational practices. The generation of power and 132 kV transmission system at Attabad will be managed by NPCC and the DCS in control room of Powerhouse will be responsible for station control and instrumentation requirements.

NPCC will be responsible for the overall generation and transmission management associated with the Project, while the station DCS will be responsible for the overall station control and instrumentation requirements as well as interfacing with NPCC through appropriate hardware.

All the important plant parameters like active and reactive power of generators, and transmission lines, station frequency, busbar voltage, reactors disconnect switches and faults alarms will be monitored remotely.

The plant DCS shall monitor and display position of circuit breakers, isolators, all local/remote switches for generators and circuit breakers and indication of Automatic Load Frequency Control (ALFC) etc.

12.19.4 SCADA Facilities for Tele-Control by NPCC

To enable NPCC to control selective key parameters of the Attabad Lake Power Plant, the following two alternative methods have been considered:

Alternative-1

This alternative is an extension of the existing hierarchical SCADA system based on front end computers deployed at NPCC Islamabad. It deploys conventional Remote Terminal Units (RTUs) serving the NPCC SCADA System and is independent of the station DCS at Attabad.

The SCADA requirements will be handled by two separate RTUs, one for monitoring and control of the Powerhouse and one for monitoring and control of 132 kV Switchyard.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Inter RTU communication shall be provided, if required. The RTU in the powerhouse will be configured in the most effective manner, for example:

- As a separate RTU, or
- As a distributed input/output module from the AIS RTU, or
- As a “slave’ unit scanned by the AIS RTU.

The RTU equipment will be capable to cater for future requirements of Powerhouse and switchyard augmentation.

For the measurements of MW, MVAr, kV and frequency etc., separate transducers will be provided in the SCADA Interface.

Advantages

Since the RTUs would be obtaining their own information from the field mounted sensors and transducers, a breakdown in the station DCS would not hamper the flow of information from the field.

Alternative-2

This alternative comprises hardware establishing an inter-computer data communication link bridging the station DCS with front end computers hosting the NPCC SCADA applications. A redundant gateway controller/inter-center communication controller, for data inter-change between the station DCS and the SCADA master system at NPCC Islamabad will be installed in the station control room for monitoring and control of the station equipment under SCADA. Dual processors configured as online and hot standby with duplicated database and operating system will be employed in the gateway controller. The gateway will interface with DCS equipment through dual redundant communications infrastructure Gateway or Inter-center communication controller fulfilling all aspects of the communications between NPCC and Attabad Lake HPP Control Room.

In this alternative, no information shall be collected afresh by NPCC rather a subset of information already collected by the station DCS for station control shall be passed on through the Communications Gateway to NPCC.This would save duplication of transducer for data collection, thereby precluding additional interfacing. For reliability, both path and media redundancy shall be deployed for data communication between the station DCS and NPCC utilizing PLC, optical fiber or alternate telecommunication means.

The amount and type of information exchanged between the station DCS and NPCC shall be a software configurable parameter of the gateway controller. The authorization of 132 kV circuit breakers control will be from the NPCC and the station DCS will only monitor the status of circuit breakers. However, this authorization can be set to local control during emergencies or maintenance. The authorization of each 132 kV circuit breaker control will be set individually from the DCS operator console. The selectable authorization levels shall be SCADA, DCS, or local. Similarly, the assignment of ALFC authorization of each generator will also be done from DCS.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12.19.5 Local/Remote Switches

"Three position" (i.e. SCADA/DCS/Local) switches will be provided in the local control panels of 132 kV switchgear equipment and the generator/governor local control panels (LCP) for the 11 kV circuit breakers and generating units respectively.

12.19.6 SCADA Control Philosophy

Normally the operation of 132 kV circuit breakers will be from NPCC and the switchyard DCS will only be monitoring their status. However, during emergencies or maintenance, the control authorization of circuit breakers will be set on local control (either station DCS or local control panel). The authorization of each 132 kV circuit breaker control shall be set from the individual three position local/remote switch (SCADA/DCS/Local).

The assignment of each generator set point control or ALFC authorization to SCADA/DCS/Local will also be done from the respective generator local/remote switch. ALFC control from NPCC will be either in the form of a set point value or increase/decrease command to the unit's governor. Operation of the plant local/remote switches will be authorized from NPCC.

RTU communication with NPCC Front End Computers will be through duplicated data channels along the PLC/fiber optic links.

12.19.7 Telecommunication System

Dual play data transmission media for transmission of speech, facsimile, data (including energy metering) shall be set up between NPCC and Attabad Lake Powerhouse. Tele protection channels, provision of telecom equipment for power interface with existing NTDC operational telephone network for operational traffic between Attabad Lake HPP and NPCC/existing stations, along with the facilities to meet the administrative traffic for the Power Complex shall also be set up as part of the Telecommunication system.

12.19.7.1 Powerhouse Communication

A communication system consisting of Local Area Network (LAN), digital telephone system (PAX/PABX), VHF radio systems and station clocks will be provided for communicating the power house with intake, switchyard, and residential camp and outside.

A digital telephone network has been planned to be installed in the powerhouse to cover the entire plant (powerhouse, switchyard, intake, the residential camp and outside).

Each generating unit will include at least one noise cancelling telephone per floor. And also step up transformer area will be provided with noise cancelling telephone sets. The outside telephones will be weather proof and installed in the switchyard and other appropriate locations. All offices, workshops, ventilation rooms, battery charger rooms etc., in the power house will be provided with telephone extensions from the digital telephone system.

12.19.7.2 Power House Intake Communication

A fiber optic cable clamped to the 11 kV feeder from powerhouse to intake has been planned to be used for communication purpose. This will have advantages in reliability, quantity of

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

information which can be transmitted and most important no problems with electro-magnetic compatibility which outweighs by far its higher price.

A backup digital radio communication link will be provided from powerhouse to intake for communication and protection purposes.

12.19.7.3 External Communication

WAPDA uses Power Line Carrier (PLC) for its communications between powerhouses and the load dispatch centre. The coupling is done between one phase and earth which makes it necessary to install for each communication line, one-line trap and one coupling capacitor at each terminal.

The location of the equipment will be partially in the switchyard and partially in the area of the control room. The 50 VDC communication supply will provide necessary power when there is a power failure in the normal auxiliary supply.

This system will give the possibility for voice and signal transmission on 132kV line between the remote powerhouse and the load dispatch center.

The control room will be additionally connected to the public telephone system to guarantee the communication with the power plant in case of failure of the PLC system.

12.19.8 Teleprotection

For 132 kV transmission lines emanating from the Powerhouse, duplicated teleprotection channels will be provided for high speed direct tripping (for breaker failure and reactor protection) and permissive tripping (for distance protection) of lines along with blocking of tripping. In order to achieve maximum security and redundancy, the direct tripping signaling will utilize different equipment to that used for permissive/blocking schemes. The teleprotection signals will not interfere with the speech signals. The equipment for teleprotection will have the flexibility for transmission over any communication medium i.e. PLC or OPGW.

12.19.9 Public Address System

For announcement and instructions to the staff in the Powerhouse area, a Public Address system shall be provided which consist of a central power amplifying unit/ and a number of microphones and loudspeakers.

Control consoles with microphones will be provided in the CCR and in each local control area. The complete system will be modular in structure. The system will be capable of selecting a single loudspeaker or a group of speakers.

12.19.10 Un-Interruptible Power Supplies (UPS)

A 48 V DC UPS system will be provided for SCADA & telecom equipment to remain functional and operative at all times. The UPS will supply the loads for PLC, Fiber Optic Terminal, RTU, Teleprotection, PABX, PAX and public address equipment. The UPS system will be fully redundant and will comprise duplicated battery chargers, battery banks and DC distributed boards to supply the loads.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12.19.11 Time Synchronization

A station clock system will be provided to ensure constant time keeping across the plant. A master clock will use local time and be synchronized using the Global Positioning System (GPS). The master clock will run slave clocks installed at key locations around the powerhouse especially on the generating unit panels. For tagging of events

satellite based Global Positioning System (GPS) with accurate time synchronization, will be utilized with time receivers at Powerhouse and NPCC. These receivers will communicate with Powerhouse and NPCC master clock system.

12.19.12 Video Surveillance System (CCTV)

The Video surveillance system shall comprise CCTV cameras, power supplies and video recording equipment enabling selected locations of the power house premises to be monitored remotely from the control building. The objective of video surveillance system shall be to monitor the entry/exit gates, boundaries, power house premises for security purposes.

The closed-circuit television (CCTV) system will be provided to monitor the condition and status of the project area remotely from the control room of the main control building. The following places

- Intake structure
- Powerhouse
- Entrance gate
- Erection bay (entrance of powerhouse)
- Machine bay
- Essential rooms
- Transformer and 132 kV AIS
- Unit transformer room
- Entrance gate of switchyard
- Entrance of main control building

Video archives for past seven days shall be maintained to facilitate post facto analyses of any untoward incidents. System design shall be flexible to permit future extension of the system. This subsystem shall comprise of the following major components:

a) Video cameras

b) A network video recorder capable of storing video bit streams generated by each camera of up to the last seven days.

The CCTV system shall be extended according to the requirements.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

13 TRANSMISSION LINE STUDY

13.1 GENERAL

This chapter aims to summarize the interconnection of 54 MW Attabad Lake Hydropower Project (being proposed at Attabad Lake on Hunza River in Hunza District) to Regional grid through 132 kV transmission line network.

The main objective of the transmission system studies is to ensure that the power plant could be connected to the proposed 132kV regional grid at Aliabad and Sost, in a safe, cost effective and reliable manner.

The Northern Areas of Pakistan, located at the gateway to China, Central Asia, Afghanistan and India, are spread over mountainous regions with world's famous mountain ranges of Himalaya, Karakoram and Hindukush. It covers an area of more than 72300 km². The population settlement is normally near the confluence of small streams with main nullahs and the river. In some cases, it also exists inside the valleys where the nullahs have mild gradients with morainic deposits. Slopes of the streams and the tributary rivers, creates tremendous potential that can be harnessed to get cheaper renewable source of energy for feeding to the regional as well as the national grid.

Transmission system of an individual project can only be developed in an appropriate manner when the parameters and layout of existing system that will be needed to satisfy the production and demand of the area, for a certain planning horizon is available. Unfortunately, there exists no comprehensive and integrated transmission network in the entire northern areas, hence no proper data is available that can provide the basis for the planning of transmission system. However, Water & Power Dept. GILGIT BALTISTAN has made a plan to establish certain parameters for the future planning of transmission system in the area.

To cater with the growing energy needs of the area, transmission of power from the national grid to the northern areas can be considered as one of the possible options. But the most suitable option to meet the immediate energy needs of the area, is the rational exploitation of renewable energy sources in the area.

Attabad Lake Hydropower Project is one among these identified run of river schemes that can be developed for the regional grid. The project is located in Attabad area at Hunza river, at a distance of 27 km from Aliabad and 120 km from Gilgit. In order to evacuate the power generated by the project, and taking into account the technical and economical parameter, a regional transmission network shall be developed, to link effectively, the load centres that can efficiently absorb the energy. The surplus power shall be required to transmit to the regional grid in Gilgit through the interconnection network of 132 kV transmission lines.

Currently, entire region of Gilgit Baltistan is facing the shortage of electricity. Water & Power dept. of GILGIT BALTISTAN has prepared the plan to meet the demand by installing new hydropower projects with the commissioning and upgradation of transmission network. In this scenario, Attabad Lake HPP will help out to meet the energy demand in Hunza and other cascaded districts.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Following are the necessary activities to establish basic project parameters / information on which the whole transmission line project will be based.

- Identification of tentative transmission line route from Attabad to the nearest load centers.
- Study and analysis to select the main components e.g. conductor, tower's type, insulator' type & strength and related hardware.
- Quantification of different components of transmission line.
- Development of cost estimate.

13.2 EXISTING GILGIT BALTISTAN TRANSMISSION SYSTEM

Gilgit-Baltistan lies between longitude 73 degree and latitude 35 degree and the population of about 1.5 million people spread over an area of 72496 sq, km. Topographically the region is mountainous and hilly surrounded by the ranges of Karakorum, Himalayas and Hindukush with deep gorges and narrow valleys. The region is not connected with the national grid due to its mountainous terrain, non-availability of high-power transmission line system and extreme weather conditions. The electricity demand of the area is mostly met by developing isolated micro and small hydro power stations having capacity 0.4-18MW installed on various rivers and nullahs. Electric power so generated is transmitted through 66KV, 33KV and 11KV overhead transmission lines and distributed through 400V LV distribution system on off grid basis.

13.3 ESTABLISHMENT OF REGIONAL GRID

Presently Gilgit-Baltistan area grid of 140 MW capacity is operating in many islands and is not connected to any grid system. There was need of assembling the data and model the present grid system and plan the interconnection along with new incoming large hydro plants. Presently the power network is based on off grid and the aim of the project is to bring them on one-grid in the region and readiness for further connection to the National Grid.

The main objectives are as under:-

Reduction of the present power loses of over 35% to the allowable limits.

Efficient management of power supply in Gilgit-Baltistan due to interconnection of all the power stations and increase of diversity factor.

Development of HPPs at the most promising sites due to availability of high voltage transmission network.

Connection to the National Grid would be possible for evacuation of surplus power to the National Grid to meet the shortage at the National level.

Attraction to the private sector to invest in the hydro power sector on IPP & PPP modes to supplement the National Grid to overcome energy shortage and to minimize subsidy and circular debt.

The regional grid would further be connected to the National Grid for evacuation of surplus power and to attract private investors to develop HPPs at the most promising sites in the region to meet the energy shortage at the National level. High voltage transmission lines of 132 KV

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

and 66 KV along with grid stations have been proposed according to the feasibility study conducted through an independent consultant.

13.4 PARAMETERS FOR TRANSMISSION LINE STUDY

Transmission system of an individual project can only be developed in an appropriate manner when the parameters and layout of existing system that will be needed to satisfy the production and demand of the area for a certain planning horizon is available. Unfortunately, there exists no comprehensive and integrated transmission network in the entire northern areas, hence no proper data is available that can provide the basis for the planning of transmission system. However Water & Power Dept. GB has made a plan to establish certain parameters for the future planning of transmission system in the area.

Following are the necessary activities to establish basic project parameters / information on which the whole transmission line project will be based.

In coordination with Water & Power Department Gilgit-Baltistan, identification of transmission line route from Attabad to the nearest load centers.

Quantification of different components of transmission line.

Study and select the main components e.g. conductor, towers, insulators and related hardware.

Development of cost estimate.

13.5 TRANSMISSION LINE FROM ATTABAD LAKE HPP

The power generated by the Attabad Lake Hydropower Project shall be mainly supplied to the load centers in the central Hunza, Aliabad and the upper Hunza (Sost) through 132 kV transmission lines. The transmission line from Attabad Lake HPP to Aliabad & Sost shall fulfill the transmission requirements keeping in view N-1 contingency and transmission of power generated by the expected future hydro power projects. A double circuit 132 kV transmission line of 27km will be connected to the proposed Aliabad Grid station to further disperse the power in the Regional Grid Network (RGN).

Alongwith double circuit 132 kV transmission line to Aliabd, a 132 kV single circuit of 70 km transmission line is also proposed upto the existing 33kV grid station Sost which is already in operation to cater for the domestic electricity demand and likely to be upgraded to 132/33/11 kV grid station. Govt. of GB is planning to make the Sost area industrialized and a dry port there in upcoming years. In the route of Aliabad to Sost, population is less and scattered therefore to meet the domestic electricity demand, already existing 33 kV line will be used to disperse the power from Sost to upper and lower nearby populated areas.

Aliabad is the commercial and administrative centre of Hunza district. Water and Power Dept. (GB) has proposed the 132/66/11 kV, 55 MVA capacity grid station in the Aliabad. There are 3 suitable sites located aside the bank of Hunza River passes near to Aliabad Town. The coordinates of these sites are listed below:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Alliabad Grid Station	Longitude	Latitude
Site 1	74°38'6.65611"/ 74.6241230583	36°18'8.71248"/ 36.3024201327561
Site 2	74°38'6.65611"/ 74.6351822536	36°18'34.36322"/ 36.309545339016
Site 3	74°38'7.22723"/ 74.6353408969	36°18'33.69423"/ 36.309359508971

All sites are located above the river water surface level. The studies regarding flood dangers will be carried out at design stage by Engineer. Large gravels are found at sites 1 & 2, while site 3 is located on plane ground. Final site to construct the Grid station will be selected by Water and Power Gilgit Baltistan.

13.6 TRANSMISSION VOLTAGE

As per Pakistan's Grid Code, the voltage of all the busses under normal operating condition should remain within the bandwidth of +8% to –5% of Nominal System Voltage. Under (N-1) contingency operating conditions, the voltage variation shall be in the range of +10% and –10% of Nominal System Voltage.

132 kV will be most suitable and economical to transmit power of 54 MW from Attabad-Lake Hydropower Project to Aliabad & Sost grid stations as the same voltage level (132 kv) has been selected for up-gradation of regional grid.

13.7 LOADABILITY CHARACTERISTICS

Load ability or transfer capability of transmission line depends upon the following:

- Voltage of the system
- Length of the transmission line
- It is represented as a percentage of its Surge Impedance loading (SIL) permissible with in the allowable voltage drop, thermal and stability limits.
- An increase in power (current) in a line will:
- Increase I^2R loss and hence temperature of the conductor denoted
- Cause increase sag of the conductor.
- Increasing sag decreases the clearance to the ground of conductor.
- Increase the voltage drop.
- increase the transmission line angle.
- All the above mentioned factors limit the maximum power transfer capacity of the transmission line. In fact, the governing limitations are different for different lines depending on:
- Line length
- Type and degree of compensation
- System characteristics / conditions

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

According to the universal load ability curve for overhead transmission lines, load ability for a transmission line of 80 km length is 3.0 times its SIL (Surge Impedance Loading) and increases exponentially for lines of length shorter than 80 km.

13.8 NUMBER OF CIRCUITS

Numbers of circuits for a power transmission line are determined by the power carrying capacity of a particular voltage level over the required distance. Transmission line loadings should not exceed 85% of their normal ratings under steady state operating (normal) conditions. Under outage/contingency conditions, the transmission lines may be loaded up to their short term or emergency ratings which are equal to their SIL (Surge Impedance Loading) or thermal ratings depending upon the line length involved.

A double circuit transmission line is envisaged from Attabad to proposed Aliabad grid station, which will further disperse the power in the Regional Grid Network (RGN).

The double circuit transmission line to Aliabad will be necessary keeping in view the 'N-1' criterion as well as possibility of induction of additional power from future power projects in the area, The option of single circuit is also otherwise not feasible because system voltage and stability will remain at stake even under normal operating conditions, if full capacity of about 130 MW on 132 kV line is utilized with future local generation.

A single circuit with N contingency is proposed to transmit the power Whereas, from Attabad Lake HPP to Sost.

13.9 TRANSMISSION LINE ROUTE

Detailed visits of the project area concludes that the possible transmission line route will be along KKH road/ Hunza River depending upon the accessibility to the transmission line route while no alternate route is available. The whole terrain is mountainous with steep gorges and tight bends on the road. The areas along the route may be subjected to snowfall on some sections from the project site to the load centers.

Access to the tower sites during execution phase will mainly be possible from the existing road. At some places the tracks / kacha roads exist which may require repairs, along with construction of new approaches for transportation of construction machinery and line materials. In order to overcome certain constraints, the line may have to be crossed to the other bank of Hunza River. Few locations may not be accessible; in such cases material will have to be transported to site through alternate means.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

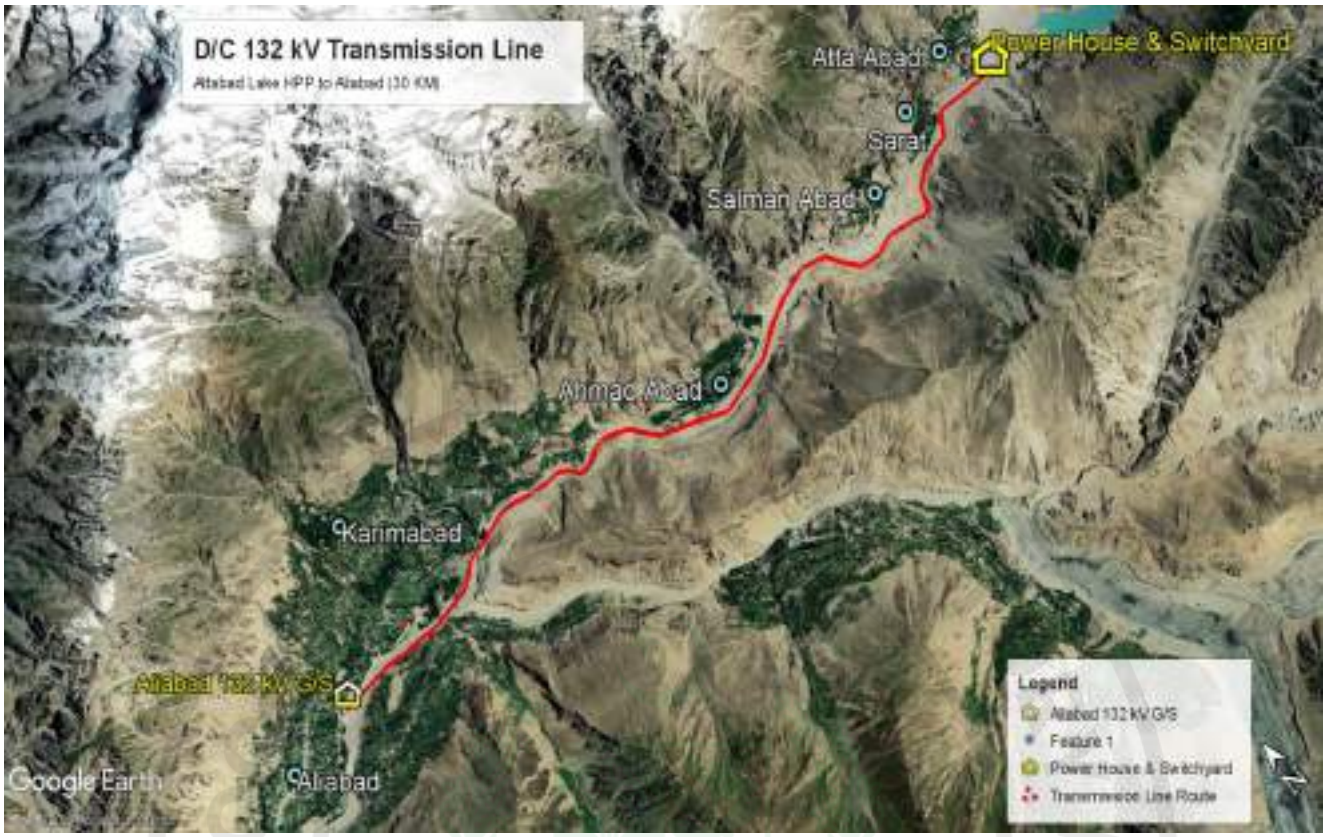

Figure 13-1 Transmission line route -Project Site to Aliabad G/S

The types of rock observed along the line route corridor are suitable for tower foundations on hill slopes. Controlled blasting will also be required both for making approaches and constructing tower foundations. In view of the prevailing terrain and environmental conditions along the proposed line route, careful design considerations such as providing higher ratio of angle towers to suspension towers along with its extent, shorter spans, insulators of suitable type and higher strength and related hardware of compatible strength are required.

Detailed survey followed by preparation of plan & profile drawings and spotting of towers will however be done separately during the detail design stage.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Figure 13-2 Transmission line route -Project Site to Sost G/S

13.10 CLIMATIC CONDITIONS

The Gilgit / Hunza River basin falls in the “subtropical continental high lands” climatic region. The weather of the area is characterized by moderate summer and severe winter. The winter season starts from November and extends up to April, and summer from May up to October. The temperature data of areas is presented in Table 13-1.

Table 13-1 Monthly Max. and Min. Temperatures

Location	Mean Monthly Max.	Mean Monthly Min.
Attabad	25° C	- 10° C
Hunza	30.6° C	- 8.0° C
Gilgit	36.1° C	- 2.7° C

13.11 SELECTION OF CONDUCTOR

As a normal rule, the conductor of a double circuit transmission line is selected on the following basis:

- The conductor should be capable of carrying the desired quantum of power under normal operating conditions, as well as under the situation of contingency outage of one of the two circuits.

- It should be strong enough to withstand extra loadings due to ice and wind pressure.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- It should be helpful in improving system operating conditions, including voltage profile, phase shift / stability, power losses etc.

Selection of conductor for the line has been done through comparison of Lynx, Panther and Rail conductors, which is presented in Table 13-2.

Table 13-2 Comparison of ACSR Lynx, Panther and Rail Conductors

Sr. No.	Description	ACSR LYNX Conductor	ACSR Panther Conductor	ACSR RAIL Conductor
1.	Number and diameter of each aluminum strand (mm)	30/2.79	30/3.00	45/3.70
2.	Number and diameter of each steel strand (mm)	7/2.79	7/3.00	7/2.47
3.	Overall diameter (mm)	19.53	21	29.61
4.	Area of cross section of aluminum (mm^2)	183.4	212.10	483.43
5.	Area of cross section of steel (mm^2)	42.77	49.40	33.43
6.	Total area of conductor (mm^2)	226.17	261.50	516.86
7.	Weight (Kg / Km)	842.4	973.8	1600.2
8.	Ultimate tensile strength (Kg)	8483	9410	11749
9.	DC resistance (Ω/ Km)	0.1580	0.1363	0.0600
10.	Current carrying capacity at 40° C (min. at w nd vel. of (m/s) (Amp)	330	367	626
11.	Power loss (W/Km/Amp)	0.474	0.408	0.180

13.11.1 TENSILE STRENGTH

The above comparison shows that the ultimate tensile strength of Rail conductor is around 38% & 24% higher than that for Lynx & Panther conductors, respectively. Hence, Rail conductor will be more reliable and secure in difficult terrain encompassing high mountains, steep gorges, sharp bends & difficult crossings as well as high to low degree of snowfall & wind pressure along the proposed transmission line route.

13.11.2 POWER TRANSFER CAPABILITY

The current carrying capacity of Rail conductor is around 90% and 70% higher than that for Lynx and Panther conductors, respectively.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

One circuit of Rail conductor will accommodate safely up to 130 MW with acceptable voltage and other system conditions. Hence, in case of outage of one circuit from Attabad Lake HPP to Aliabad, other circuit with rail conductor will not only accommodate full power of 54 MW from Attabad-Lake Hydropower Project but will also have provision of accommodating additional power of other possible future power projects in the area.

13.11.3 POWER LOSSES

Power loss through Rail conductor will be about 62% and 56% less compared to that for Lynx and Panther conductors, respectively.

13.11.4 RECOMMENDATION

Due to the above mentioned advantages, it is recommended to use Rail conductor for the subject. Rail conductor will be in accordance with WAPDA / NTDC Specification No. P-50:88.

13.12 TOWERS

13.12.1 TYPE AND BASIC DATA

Towers will be as per WAPDA / NTDC Standards and Specifications applicable to double circuit & single circuit 132kV transmission line using Rail conductor.

Types of these towers as designated in the Specifications are “ZM-1”, “ZM-30” and “ZM-60”. “ZM-1” is Suspension tower whereas “ZM-30” & “ZM-60” are Angle towers. Basic data of these towers is as follows:

ZM-1

Deflection Angle	30^0
Wind Span	230 m
Weight Span	260 m
Weight of the basic tower	4275 kg
Weight of 3 m Leg extension	708 kg
Weight of 6 m leg extension	1400 kg

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

ZM-30

Deflection Angle	30^0
Wind Span	230 m
Weight Span	260 m
Weight of the basic tower	6415 kg
Weight of 3 m Leg extension	1242 kg

ZM-60

Deflection Angle	60^0
Wind Span	230 m
Weight Span	260 m
Weight of the basic tower	8594 kg
Weight of 3 m Leg extension	1739 kg

13.12.2 TOWER CONFIGURATION

WAPDA/NTDC Standard configuration will be used as much as possible. This shall facilitate design, erection, maintenance, stock, etc. and shall also use the organizational experience in construction, operation and maintenance. Therefore the existing WAPDA/NTDC drawings for double circuit & single circuit 132kV are to be taken as base.

The new tower configuration has to consider the behavior of conductors and earth wires in different Zones under the conditions with and without ice, under wind acting on them and considers the movement of conductors due to dropping of ice.

To minimize stresses in earth wire peaks at suspension towers due to unequal span length or unequal additional loading. It is recommended to clamp the earth wires by V frame with approximately 0.7m length at the tension tower peaks. This would prevent grid mounting and allows balance of difference in tensions. For the new tower configuration it is assumed that sag and ground clearance shall be the same as for standard 132kV lines built so far.

It is assumed that towers will need increased internal clearance to consider different behavior of conductors under the no load and load conditions as well as the unequal dropping down of accretions.

13.12.3 MIX OF DIFFERENT TYPES OF TOWERS

The numbers of each type of tower shall be finalized as per site during the detail engineering design.

The ratio of suspension tower to angle tower come out to be 30: 70 as compared to the ratio of 80: 20 generally used in plain areas. The low ratio of suspension towers to angle towers will be one of the most important factors with respect to the reliability and security of the subject transmission line along the difficult route involving difficult, mountainous terrain, steep gorges and sharp bends. Provision of appropriate number of WAPDA / NTDC Standard 220 kV towers of types EA, ED & EG, respectively, is also recommended for use specially at locations involving crossings of steep gorges, river etc.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The average span shall be based on the site conditions during the detail engineering design stage. The important aspects for length of span are however are the acceptable margin of safety, additional estimated combined loading of up to 25 % on towers due to ice accretion. If required, the spans can be further reduced for line stretch in high ice zone and with longer spans in low ice areas, during project execution stage.

As mentioned earlier, the task of detailed survey, preparation of plan and profile drawings and spotting of towers will be undertaken during the project execution stage. Type of tower and span at each identified location throughout the line stretch will also be determined and finalized with the approval of the Engineer.

13.12.4 ADDITIONAL LOADINGS DUE TO ICE AND WIND

During extreme winters, additional combined load on towers due to ice accumulation on conductor, insulators and cross arms is expected to be up to 25 % of normal loading, ranging from maximum to minimum between project site to load centers.

The number and mix of angle to suspension towers with much reduced spans will help sustain the additional loading on towers due to ice and wind. However, larger foundation base may be essential requiring design of new towers and tower foundations to withstand simultaneous impact of ice and wind pressure especially in the high ice zone. This aspect should be got checked by NTDC, based on their experience of existing transmission lines in the similar areas.

If concerns about stability of towers against extreme ice and wind conditions could not be resolved, then employer should consider awarding this project on EPC basis wherein the contractor will also be responsible for design of new towers and associated foundations, if needed.

In any case, design and testing of new towers is highly specialized and an independent task which is not covered under the present scope of work.

13.12.5 WAPDA / NTDC SPECIFICATIONS

For proposed towers, the related WAPDA / NTDC Specifications are as under:

Fabrication of Steel Structure	P-139:80
Zinc Coatings	P-82:81
Steel Nuts and Bolts (Inch Series)	P-19:83
Barbed wire	P-162:81
Danger & Sign Plates	P-104:76
Steel Washers	P-20:68

13.12.6 FOUNDATIONS

Tower foundations will be in accordance with WAPDA / NTDC Standards and Specifications.

Foundation type and design will be corresponding to each type of Standard tower used.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Geotechnical investigations for construction of foundations will be carried out during the project execution stage. Foundations will be classified as normal, pile, rock-anchor, or any special foundation not covered in the WAPDA / NTDC Specifications.

For each foundation, each type of foundation will be identified during project execution stage which will be reviewed / approved by the Engineer. The design and method of construction for any special foundation not covered in the WAPDA / NTDC Standards will also be submitted to the Engineer for review / approval.

13.12.7 INSULATORS

In order to avoid flash-over due to ice and fog, Fog type porcelain insulators are recommended to be used. In normal areas, insulators of 80 kN strength are used on 132 kV transmission lines in NTDC system. However, because of difficult conditions associated with route of the subject transmission line, Fog type insulators of 100 kN strength have been considered to make the line completely reliable and secure. 8 numbers of insulators per string is recommended. The Fog type Insulators will be in accordance with WAPDA / NTDC Specification No. P-8:96.

The WAPDA / NTDC Specifications for insulator hardware will be as under:

Suspension Strings:	P-140:82
On Strings	P-143:82

13.12.8 MISCELLANEOUS ITEMS

Miscellaneous items of transmission lines will be according to the following WAPDA / NTDC Specifications:

Galvanized Steel Wires	P-12:80
Earth Wire Fittings	P-141:80
Mid Span Joints and Repair Sleeves	P-144:80
Stock Bridge Vibration Dampers	P-142:83
Grounding Material	
Earth Rod	P-116:81
Copper Wire for Earthing	P-16:68

13.13 OPTICAL OVERHEAD GROUND WIRE (OPGW)

In order to protect the transmission line and grid station equipment from lightning and to transmit the protection and communication signal optical ground wire will be provided.

The main features of the cable will be

OPGW size	70 mm2
Outer diameter	11.4mm
Breaking load	8000kg
DC resistance at 20^{o}C	1.02 ohm/km

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Nominal weight	458kg/km
Number of fibers	at least12

13.14 ENVIRONMENTAL ASPECTS

In high voltage range, the conductor selection is based on

a) Corona losses
b) Radio interference (RI)
c) Television interference
d) Audible noise (AN)

13.14.1 CORONA LOSSES

The effect of increasing the operating voltage of a line as its critical surface gradient (21.2kV/cm) is approached, is producing power losses in the lines and causes the conduc tor to generate emanate higher frequencies causing radio and television interference.

For Attabad-Lake HPP transmission line, the conductor diameter will be higher than the permissible limit. In view of the rail conductor, there will be no problem of corona, radio interference and television interference.

13.14.2 AUDIBLE NOISE

Up to 220 kV level, the audible noise generated by transmission lines is usually no concern. The level of AN generation with conductor design which satisfies the RI requirements sufficiently low.

13.14.3 Surface Gradient

The clearance between overhead transmission lines and nearest objects are set primarily to avoid any possibility of flash over. The proposed design ensures that there will be no problem of surface gradients causing charging current through the human body or passing vehicle.

13.15 MINIMUN CLEARANCE OF 132 KV TRANSMISSION LINE

The minimum clearance of the proposed 132 kV overhead line is as follows:

i.	132 kV lines across country	6.71m
ii.	Over roads and highway	7.92m
iii.	Over rivers and canals	9.14m
iv.	Minimum clearance from building Vertical	5.18m
v.	Horizontal	6.10m

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

14 PROJECT QUANTITIES AND COST ESTIMATES

14.1 GENERAL

The cost estimates form the basis of the economic and financial evaluation of the Project. These have to be prepared on the basis of representative unit rates for the various construction activities and the respective quantities. The estimation of cost for Attabad Lake Hydropower Project (ALHPP) has been carried out on the basis of Feasibility Drawings.

The cost estimate for ALHPP covers quantities and costs for Preparatory works, Environmental Mitigation, Civil and Electrical & Mechanical (E&M) works. Civil Works items such as earthwork, concrete, reinforcement, shotcrete and grouting, etc. have been estimated based on Feasibility Drawings. Rates adapted are based on WAPDA Composite Schedule of Rates, Material based Survey Rates and recently tendered WAPDA Projects.

14.1.1 Basic Assumptions

Few assumptions are always made in cost estimation. For this costing, following assumptions and exceptions are considered:

- No allowance has been kept in the rate analysis for price escalation. All rates have been evaluated on March, 2021 prices.
- Project layout and alignment of structures will not change.
- The survey on which the whole study has been according to prevailing International Standards.
- Specifications for the construction would be according to prevailing International Standards.
- Land acquisition of the Project Area and other pre-construction activities will be completed before Contractor's mobilization.

14.2 COST ESTIMATION

Cost estimation of any Project or its component is based on two factors; one is Quantity and the other is Unit Rate. The cost estimates for various works including Preparatory works, Civil and E&M works have been prepared by multiplying unit rates with the relevant quantities of different items.

14.2.1 Price Index

For Local & Foreign cost component the rate of 1 US$ = Pak Rs. 157 of March, 2021 price level has been adopted.

14.2.2 Development of Unit Rates

To develop the unit rates, the operating cost of the equipment, labour and material cost has been worked out from basic data.

Rental and Operating Cost

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The operating cost of the equipment are worked out which includes the rental cost of machinery, operators' charges and fuel, lubricant and minor repair costs.

Labour Cost

The rates of wages for the skilled, un-skilled and operators for various construction equipment are required to work out operating cost. The selected rates are based on market wages in Hunza District. These rates are based on 8 hours of work per day.

i. Rental and Operating Cost

The operating cost of the equipment are worked out which includes the rental cost of machinery, operators' charges and fuel, lubricant and minor repair costs.

ii. Labour Cost

The rates of wages for the skilled, un-skilled and operators for various construction equipment are required to work out operating cost. The selected rates are based on market wages in Hunza District. These rates are based on 8 hours of work per day.

iii. Material Cost

These costs fall under two categories:

- Manufactured items: e.g. cement, POL, steel, etc. The unit rates taken for these items are ex-factory rates including transportation to the site.
- The other category includes concrete aggregates and riprap which are readily available at site. These materials will be processed in size as per requirement at site and used. Local market rate has been taken for these materials for rate analysis.

14.2.3 Rate Analysis

Rate analysis for each major item of work includes the rates for individual machines involved in a process, generating composite rates for each major item of works by combining the required number of different machines to develop a workable group and loading it with necessary operators/drivers and materials.

International price for the major equipment were used including its transportation from Karachi port to Project site. Duties and taxes are not included in the equipment cost as it is considered feasible by many foreign contractors to procure the machinery on import/re-export basis by submitting the guarantees against duties and taxes. Bank charges for these guarantees have been accounted for in the computation of Contractor's indirect cost.

Transportation of equipment from Karachi to Project site has been estimated on the basis of cargo handling charges through existing roads. On the basis of rates selected earlier for labour, material and operating equipment, the unit rates for each item is then derived. Specified field conditions are taken into consideration. Provision of overheads, idle hour, supervisions staff cost and contractors profit has been taken while working out the equipment and labour cost components. It has been assumed that:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Work will be carried out for 8 hours per day and
- 26 working days per month

14.2.4 Basis for Unit Rates

The Project cost is sensitive to the unit rates. Thus, care has been exercised in deriving the unit rates. Unit rates for most of the items of Civil Works of ALHPP have been estimated using rates analysis method. The rate analysis for several items of Civil Works such as excavation, structural reinforced cement concrete, plain cement concrete and, shotcrete have been derived and applied to the quantities for cost estimation. For certain items, the unit rates have been compared and checked with the rates of recently WAPDA tendered projects. The WAPDA Composite Schedule of Rates, 2013 has also been consulted. For some of items related to Project, due escalation has been applied for price level of March, 2021 to arrive at most reasonable and realistic rates.

Cost of E & M equipment is based on budgetary prices from reputed manufactures, both local and foreign. The following factors have also been assumed during the development of Civil and E&M works cost estimate:

- Construction of major civil works and installation of majority of the E & M equipment will be performed using Pakistani or an equivalent cost competitive labor force; and
- Where feasible, equipment fabrication will be carried out locally. Locally produced items could include trashracks, stoplogs, embedded parts and the rolling & welding of steel manifold.

Unit rates adopted for different items are presented in Table-14.1.

14.2.5 Civil Works Quantities

Civil works quantities for cost estimate have been calculated using Feasibility Drawings consisting of plans and sections of all the Project components. These drawings are presented in Volume-2 of Feasibility Report. Efforts have been made to estimate the quantity of each major items of each Project component with accuracy.

Major portion of the Civil Works estimate includes calculations for earthwork, concrete and reinforcement etc. For the major structures such as Main Weir, Sediment Flushing Channel, Power Intake, Low Pressure Headrace Tunnel, Surge Tank, Penstock, Powerhouse, Switchyard and Tailrace Channel, the quantities of earthwork, concrete and reinforcement are presented in Table-14.2.

14.3 BREAKDOWN OF ESTIMATES

The basis for costing of different project components is briefly discussed as under:

14.3.1 Land Acquisition and Environmental Mitigation

Land Acquisition and Environmental Mitigation cost contains the cost of permanent land acquisition for project components, temporary land acquisition, building compensation, spoil disposal area rehabilitation, rehabilitation of villages, livelihood allowance for affectees, monitoring &evaluation and land conservation etc. The total cost of land acquisition and environmental mitigation is estimated as Rs. 208.450 Million (Ref: Table-14.4).

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

14.3.2 Preparatory Works

The items under this component includes construction of access roads within the Project area, site installations, Contractor camps, construction of camp/colony for Consultants' and WAPDA staff, construction of bridge near powerhouse. The cost for mobilization and demobilization and reservoir slope stabilization & construction risks costs are also included. The total cost for preparatory works is estimated as Rs. 952.945 Million (Ref: Table-14.5).

14.3.3 Main Weir

Estimate for Main Weir includes construction of Main Weir itself along with the construction of upstream and downstream coffer dams to facilitate the working of the main civil structures. The total cost is estimated as Rs. 2,008.821Million (Ref: Table-14.6).

14.3.4 Sediment Flushing Section

Cost of construction of Sediment Flushing Section consists of cost for clearing & grubbing, soil and rock material excavation, rock excavation, concreting, reinforcement, grouting etc. The total cost of Sediment Flushing Section is estimated as Rs. 2,326.679 Million (Ref: Table-14.7).

14.3.5 Power Intake

Cost of construction of Power Intake consists of cost for rock excavation, concreting, reinforcement etc. The total cost of power intake is estimated as Rs. 429,289 Million (Ref: Table-14.8).

14.3.6 Low Pressure Headrace Tunnel

Cost of construction of Low Pressure Headrace Tunnel consists of cost for rock excavation, shotcrete, rock bolts, concreting, reinforcement and access tunnel cost etc. The total cost of headrace tunnel is estimated as Rs. 1,820.182 Million (Ref: Table-14.9).

14.3.7 Surge Tank

Cost of construction of Surge Tank consists of cost for rock excavation, shotcrete, rock bolts, concreting, reinforcement etc. The total cost of surge tank is estimated as Rs. 132.727 Million (Ref: Table-14.10).

14.3.8 Penstock

Cost of construction of Penstock consists of cost for soil and rock excavation, shotcrete, rock bolts, concreting, reinforcement, penstock (steel liner) etc. The total cost of penstock is estimated as Rs. 713.256 Million (Ref: Table-14.11).

14.3.9 Powerhouse and Tailrace Channel

Estimate for Powerhouse and Tailrace Channel contains the cost of all the civil works for construction of Powerhouse. It covers the cost of soil excavation, earthen backfill, concreting, reinforcement etc. The total cost of powerhouse and tailrace channel construction is estimated as Rs. 708.792 Million (Ref: Table- 14.12 & 14.13).

14.3.10 Watershed Management at Shimshal Nullah

At Attabad Lake, most of the sediment load comes from Shimshal Nullah, therefore, check dams has been proposed in the Nullah for which survey and field investigation will be carried

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

out during the detailed design. An amount of Rs. 392.500 Million has been kept for the construction of 03 check dams to control the rate of sediments entering in Attabad Lake.

14.3.11 Hydraulic Steel Structures

Estimate for Hydraulic Steel Structures include procurement of power intake main gate, intake trashracks, intake trashrack cleaning machine, draft tube gates and gantry cranes. The total cost of hydro-mechanical equipment is estimated as Rs.139.730 Million (Ref: Table -14.14).

14.3.12 Hydro-Mechanical Works

This section deals with the Hydro-Mechanical Equipment which includes procurement of turbines, governors, inlet valves, powerhouse bridge crane and mobile crane, cooling water system, drainage and dewatering system, compressed air system, firefighting system & powerhouse elevators and HVAC system etc. etc. The total cost of hydro mechanical equipment is estimated as Rs. 1,690.890 Million (Ref: Table-14.15).

14.3.13 Electrical Works

This section deals with the procurement of Electric Equipment and comprises of generators, transformers (main & auxiliary), MV/LV& DC equipment, grounding, telecommunication and lighting systems, spare parts etc. The total cost of electrical equipment is estimated as Rs. 2,249.339 Million (Ref: Table-14.16).

14.3.14 Switchyard Works

This section deals with the procurement of 132 kV Switchyard Equipment and comprises of circuit breakers, communication system, control equipment, spare parts etc. The total cost of Switchyard equipment is estimated as Rs. 428.453 Million (Ref: Table-14.17).

14.3.15 Transmission Lines

This section deals with the civil works and procurement of equipment for 132 kV Double Circuit Transmission Line from Powerhouse to Aliabad and 132 kV Single Circuit Transmission Line from Powerhouse to Sost. The total cost of transmission lines is estimated as Rs. 1,500.135 Million (Ref: Table -14.18).

14.3.16 Transportation Charges

The E&M equipment for the construction of Project including turbines and generators etc. are to be imported. These equipment are to be shipped from the country of its manufacturing to the Project Site. The transportation charges of equipment have been estimated as Rs. 420.598 Million which are 7% of the E&M equipment cost.

14.3.17 Erection & Commissioning

Erection & commissioning charges have been taken as 8% of the E&M equipment cost. The cost of erection and commissioning has been estimated as Rs. 480.684 Million.

14.3.18 Engineering and Supervision

This represents the cost of preparation of tender documents, pre-qualification of bidders, evaluation of bids, review of detailed design and submittals by the Contractor, administration of the construction contract and measuring of work. The cost for engineering and supervision has been taken as 7% of the Project cost and is estimated as Rs1,229.539 Million.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

14.3.19 Physical and Numerical Modeling

The physical and numerical modeling plays a fundamental role in the analysis of the hydraulic structures behavior of a Project. A lump sum provision of Rs. 5.0 Million has been kept for model studies during detailed design.

14.3.20 Physical Contingencies

Contingencies have been included in the estimate. These need to be viewed as an integral part of the estimated construction cost. To cover some of the unforeseen that may occur over the period of construction, 3% of the costs of Civil, E&M and Preliminary works have been applied. Contingencies are estimated as Rs. 526.945 Million.

14.3.21 Admin, Audit, Accounts, Legal and Client's Expenses

Administration, audit, accounts, legal and client's expenses have been taken as 2% of the Civil, E&M and Preliminary works costs. The cost of these expenses has been estimated as Rs. 351.297 Million.

14.3.22 Authority Overheads

Factor of 1.5% has been applied on the costs of Civil, E&M and Preliminary works to cover this head and Authority Overheads cost is estimated as Rs. 263.473 Million.

14.3.23 Insurance Cost

The cost of insurance has been taken as 0.5%of the costs of Civil, E&M and Preliminary works, estimates to Rs. 87.824 Million.

14.3.24 Local and Foreign Components

The cost estimates for various works including the preliminary works, civil works, hydraulic steel structures, hydro-mechanical and electrical equipment has been further subdivided into local and foreign cost components. This job has been accomplished by consulting recently tendered WAPDA projects and prepared by multiplying factor (percentage) to the whole cost of different components.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

14.4 PROJECT COST

The total cost of the Project by summing up all the costs mentioned above is presented below:

- Total Base Cost Rs. 20,028.916 Million
- Total Base Cost US$ 127.573 Million

The summary of the Cost Estimate is presented in Table-14.3.

The Equipment, Material and Labor rates adopted are given in **Annexure – A.**

14.5 PROJECT PHASING

Estimated time for Project construction is 03 years. Accordingly, Project phasing plan has been designed to fulfill the Project needs as per requirement (Ref: Table-14.19).

Table 14-1 Unit Rates for different Items

Description	Unit	Rate (PKR)
Excavation in common material	m^3	958

15 CONSTRUCTION PLANNING AND COST ESTIMATES

15.1 GENERAL

This section covers the construction planning aspects of Attabad Lake Hydropower Project (ALHPP) in detail. The implementation schedule for the Project has been prepared taking into account the anticipated construction methods and planning. Following areas are covered in the subject section of the report:

- Project geographic location and access to the Project Area.
- Availability of manpower.
- Planning of effective working periods.
- Required Construction Materials, Storage and Major Equipment.
- Detailed Construction Planning and Methodology for different Project components.
- Project Implementation Schedule.
- Mode of Construction Supervision.

15.2 PROJECT LOCATION

ALHPP is proposed on Attabad Lake along Karakuram Highway (N-35) in Hunza Valley. The Weir Site has been proposed at existing spillway of Attabad Lake. The Powerhouse site is about 2.5 km downstream of the Weir Site, along the left bank of Hunza River.

15.3 ACCESSIBILITY TO PROJECT AREA

15.3.1 Roads Access

The ALHPP is approachable from all major cites of Pakistan, primarily Islamabad and Gilgit along the existing N-35 Karakoram Highway (KKH). KKH is 806 km long and starts at Hassanabdal in province Punjab. It passes through Khyber Pakhtunkhwa and the Northern areas and terminates at Khunjerab Pass in the Karakoram Range on the Pakistan – China border. The maintenance of the Karakoram Highway now is the responsibility of the National Highways Authority (NHA) who operates and maintains this road through Frontier Works Organization (FWO). The KKH is two lane all-weathered mountainous road. Landslides on KKH are frequently experienced during the rainy seasons, blocking the vehicular traffic ranging from a few hours to a number of days and can even extend up to a few weeks occasionally.

No major rehabilitation or upgrading has been carried out on the KKH since its completion in 1978, although some maintenance has been undertaken and its condition from Gilgit to Chilas city is good however, the condition of road from Chilas to Besham is not satisfactory. It shall be necessary to rehabilitate the existing structure of KKH to serve the construction of ongoing Dasu Hydropower Project & Diamer Basha Dam Project and proposed upstream projects including Shyok Dam, Bunji Hydropower Project and ALHPP Lake Hydropower Project etc., to

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

allow transport of construction materials, heavy construction equipment and the permanent plant and equipment.

The route from Islamabad to Thakot via KKH is through Mansehra via Haripur and Abbottabad. From Mansehra, KKH moves towards Shinkiari, Battal, Batgram and Thakot. With the construction of Motorways, Thakot can now easily be accessed through Motorways. From Thakot Bridge, the access onward to Gilgit and Hunza continues as a part of KKH:

- Islamabad to Burhan Interchange near Hassanabdal via M-1 (Islamabad-Peshawar Motorway):
- The transportation from Islamabad to Burhan Interchange near Hassanabdal via Islamabad-Peshawar Motorway (M-1) comprised of 6 lanes is 44 km.
- Burhan Interchange to Thakot via M-15 (Hazara Motorway):
- The transportation from Burhan Interchange to Thakot via Hazara Motorway (M-15) is also 6 lanes upto Haripur, 4 lanes upto Mansehra and 2 lanes upto Thakot with five Tunnels, two at Abbottabad & one each at Battal, Karmong & Mansehra, with route distance of 180 km.
- Thakot to Gilgit via N-35 (KKH);
- KKH (N-35) from Thakot to Dasu is in good condition whereas from Dasu to Chilas, the road condition is not good and requires improvements. From Chilas onwards to Gilgit, the road is in good condition. The route distance is 390 km.
- Gilgit to Project Area via N-35 (KKH) along Hunza River.
- KKH (N-35) from Gilgit to Project Site at Attabad Lake is good condition metaled road with 2 lanes. The route distance is 120 km.

There is another route from Islamabad to Gilgit and Project area via Babusar Pass, through National Highway (N-15). This route with good condition metaled road is although shortest than national highway to reach upto Chilas but due to high altitude mountains, many sharp turns and route closure for about six months in a year because of heavy snowfall during winter, the transportation through this route is not suitable for heavy vehicles.

The distances between Project Site and major landmarks are as follows;

Major Landmark	Distance (km)	Importance
Gilgit	120	Capital of Gilgit Baltistan and nearest airport
Khunjerab Pass	150	Pak-China border, trade route between the two countries
Islamabad	735	Capital of Pakistan
Lahore	1,100	Capital of Province Punjab
Karachi	2,300	Sea Port

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

15.3.2 Access by Air

Gilgit, the capital of Gilgit-Baltistan is the closest airport at a distance of 120 km from the Project Site. Air time to reach Gilgit from Islamabad is about 1 hour subject to weather. Helipads are also available which can be used in case of extreme urgency situations.

15.4 MANPOWER AVAILABILITY

15.4.1 Unskilled

Unskilled labour including drivers, guards, clerical staff, etc. will be all indigenous and mostly available from Gilgit Baltistan Region.

15.4.2 Unskilled

Adequate number and variety of skilled labour will be required for the Project. Skilled labour will mainly consist of masons, carpenters, mechanics, electricians and technicians for operating various construction equipment, batching plant, aggregate processing plant, surveying alongwith the execution of various construction activities including production and laying of concrete, rock blasting, quality control, testing of construction materials, welding, heavy equipment repair and installation of E&M equipment etc. The Project Area will not be able to provide significant number of skilled labours. However, sufficient number of manpower is available in other parts of Pakistan.

15.5 FACTORS AFFECTING PROGRESS OF CONSTRUCTION WORKS

15.5.1 Non-Productive Periods

The climate of the Project are is characterized by moderate summers and severe winters with maximum daily temperatures in summer often exceeding 30 °C and about −10 °C in winters. The Project Area receives precipitation in the form of rain in summers and snow in winters. During severe cold weather with temperature falling below freezing point, the cement and reinforcing bars cannot be stored for long periods due to deterioration in their quality. The storage of cement below freezing point will lead to its setting. Moreover, it would be difficult for supervisory and working staff to work in cold season and snowfall, therefore, the above ground construction works are expected to be suspended for about 60 days every year during January & February.

Sunday is a weekly holiday in Pakistan. Therefore, six days work in each week is expected at Project from Monday through Saturday but normally, Sundays are not observed as holiday at Projects in remote areas and the labours are allowed to avail more holidays on Eid festivals. It is traditional to close the Project Site for 7 to 10 days on Eid-ul Fitr and Eid-ul-Azha as most of the labour, who would be hailing from distant places visit their families to celebrate these festivals with them. There are 14 official public holidays in Pakistan, as shown on Table 15-1. Depending on the lunar calendar, dates of some are subject to variation.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 15-1 Public Holidays

Occasion	Date	No. of Days
Kashmir Day	05th February	1
Pakistan Day	23rd March	1
Labour Day	01st May	1
Independence Day	14th August	1
Eid-ul-Fitr*	1st to 3rd Shawal	3
Birthday of Quaid-e-Azam & Christmas	25th December	1
Eid-ul-Azha*	9th to11th Dhul-Hijjah	3
Youm-e-Ashur*	9 &10th of Muharram	2
Milad-un-Nabi*	12th Rabi Ul Awal	1
Total Official Holidays		14

(*) Dates of religious holidays are defined by the lunar calendar

15.5.2 Procurement and Storage of Materials

Cement

The Cement is abundantly available in Pakistan. During snowfall and rainy season, there is risk of supply hold-up due to inclement weather for 8 to 10 days. To ensure continuity of construction works, it is assumed that 02 to 03 weeks storage of cement at site in weatherproof warehouses will be essential. It has been estimated that about 31,485 tons cement would be required to meet the project construction activities. Mostly Ordinary Portland Cement (OPC) will be used. Sufficient production capacity of cement per day is available with the existing cement factories in Pakistan and cement can be transported to the project site using trucks or long trailers.

The Table – 15-3 indicates the present daily production of five factories in nearest locations to the project. It is evident from production rates of these factories that any of these factories can furnish the requisite quantity of cement for concrete works at the project site.

Table 15-2 Cement Production Capacities in various Factories

No.	Manufacturer	Production (tons/day) / Distance (km)
1	Bestway Cement (Farooqia)	8,155 / 675
2	Askari Cement (Wah)	3,020 / 685
3	Fauji Cement (Fateh Jhang)	9,407 / 710
4	Askari Cement (Nizampur)	4,662 / 755
5	Cherat Cement (Nowshera)	12,427 / 790

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Coarse Aggregate

As mentioned in Volume-2 Geology and Geotechnical Investigations, rock quarries have been identified at Passu and Powerhouse area. The marble present in Passu area and Rounded Boulder Gravel Silt (RBGM) at Powerhouse Area can be used as coarse aggregate by certain amount of processing, i.e. crushing, washing, screening and blending. The muck material from underground excavations cannot be used as coarse aggregate with OPC due to potential of Alkali Silica Reaction.

Sand

High quality of large sand deposits are available in the tail end area of Attabad Lake near Shishkat Bridge for use in the ALHPP.

Reinforcing Steel

The quantity of reinforcing steel required for the Project will be about 3,300 tons, with a monthly average consumption of about 155 tons. Several factories in the country produce small quantities of reinforcing steel, in the form of both plain and deformed bars. There is no factory producing reinforcing steel bars in the vicinity of the Project Site. The nearest location from where the reinforcing steel bars of the desired specification are available is Islamabad. Both hot and cold rolled reinforcing steel bars are available in desired quantity from Islamabad, about 735 km from the Project Site. The storage of reinforcing steel sufficient for one month peak consumption 155 tons will not require large areas.

Explosive Materials

In the main weir and flushing channel areas, extensive volume of excavation is of slided materials having large size boulders, which may require blasting. There are certain areas, where rock excavation would also be involved like power intake, headrace tunnel and surge tank etc. The consumption of explosives and blasting consumables is generally difficult to assess. However, a sustainable inventory will have to be maintained for which adequate storage depot will be essentially required at Project Site. The Wah - Bofors factory in Wah (near Rawalpindi) is capable of supplying all the explosives and blasting consumables required for the Project.

Steel Plates and Steel Formwork

Steel sheets of various thicknesses are produced at the Steel Mills at Karachi, which can be used to fabricate steel formwork. These can also be used for fabricating steel liners and other miscellaneous items required in connection with the construction activities. Alternatively, steel items can be imported from abroad. Most likely source of steel plate could be nearby countries such as China and Iran.

Petroleum Products

Petroleum products will be mainly diesel with comparatively minor quantity of gasoline and lubricants, which can be procured directly from the source i.e. the oil refineries, spread in the country, for the operation of machinery and vehicles. The storage tanks would be established at the Project site with total capacity of around 40,000 litres, sufficient for around one month of

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

operation, to cope with extraordinary conditions like land sliding on the KKH or fuel shortages, etc.

Water and Stone for Riprap and Fill Material

The Hunza River water will be used in the making of concrete at ALHPP. The results of water samples taken from Hunza River indicate that water is suitable for mixing & curing of concrete.

The large boulders with sufficient quantity present in the slided mass can be used as riprap material to control the erosion by water. Silty sand, sandy silt and gravelly sand available in the river bed and in slided mass (in ample quantities) can be used as fill material for the protection of slopes and construction of coffer dam etc.

15.5.3 General Construction Equipment

The economic life for most of the construction plant and equipment is five 5 to 7 years, therefore brand new equipment should be deployed on the Project. Most of the construction plant and equipment required for the execution of the works will have to be imported from international sources like excavators, dumpers, graders, crawlers, cutters, drilling jumbos, drilling and grouting equipment, batching and concrete plant, vibrators, mixers, graders, rollers, dump trucks, power generator etc.; the same applies to most of the spare parts and construction plant and equipment-related consumable supplies.

Due to the difficult KKH haulage conditions through mountainous terrain, the size of equipment will generally be smaller, with most units weighing less than 40 tons when prepared for transportation. Large items of equipment may be brought to the Project site in knock-down condition for assembling at the site.

15.6 PRE-CONSTRUCTION PHASE

Upon the completion of Feasibility Study, a number of preliminary works are required to be completed as pre-requisites for starting the construction phase of the Project including approval of PC-I, land acquisition, procurement of Consultant, preparation of EPC tender documents and the selection of EPC Contractor.

Immediately after the approval of PC-I of the Project, the Consultant will be hired for the review of Feasibility Study, preparation of EPC tender documents and construction supervision. Simultaneously, land would be acquired for project components and access roads. The Consultant, after the award of Consultancy Contract will immediately commence their pre-construction phase tasks; however the supervision period will proceed after the award of Main Contract. After the completion of tender documents by the Consultant, the EPC Contractor shall be hired to commence the preparatory works at project site. The Pre-construction activities are planned to be completed within 14 months.

15.6.1 Land Acquisition

Permanent Acquisition

No major problem is envisaged in acquisition of land. It is anticipated that land required for the Project on permanent basis will be acquired / purchased. To streamline the Project implementation and to avoid delays, it is desirable that the land acquisition process is

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

accomplished and possession of the land for temporary and Project main structures is taken at least one month before start of construction work.

Temporary Acquisition

The land required for the establishment of contractor camps, stores and workshops will be acquired on temporary basis by direct negotiation and agreement with the owners. Temporary acquisition will principally be the responsibility of the Contractor.

15.6.2 Contract Award on EPC Basis

International Competitive Bidding (ICB) has been proposed for execution of the project works for award to the contractor on EPC basis detailed hereunder:

XIII. Detailed engineering design of the Project components.

Construction of infrastructure works, civil works, procurement & installation of electrical and mechanical equipment etc.

15.7 PREPARATORY WORKS

Preparatory works includes access roads, contractor's camps & site installations and, infrastructure works, etc. It is envisaged that the EPC Contractor will mobilize its personnel and equipment to the site within 60 days after signing of Contract. The main activities to be undertaken by the EPC Contractor under preparatory works are briefly outlined below:

- Establishment of Contractor's camp and other facilities.
- Construction of Residential Colony.
- Construction of access roads to main work sites.
- Additional survey and investigations required by the Contractor.

The detailed design of temporary works and permanent structures by EPC Contractor shall also be commenced in parallel with the preparatory works.

15.7.1 Contractor's Camp

About 300~350 work force together with the supervisory staff of the Contractor will be required for the Project construction. The workforce will be originated from Gilgit Baltistan and different regions of Pakistan and from oversees. The Contractor will be responsible for the construction of adequate accommodation and temporary facilities for his workforce before the start of the main works. The Contractor also will carry out proper and adequate maintenance of such facilities to provide neat, well-kept, pleasant, healthful surroundings and conditions for all occupants.

All utilities including electricity, water supply, sewerage system and approach roads will be provided by Contractor at construction camps & offices and in residential area. The Contractor will ensure that all these facilities fulfill the requirements for residential camps, site offices, yards, construction sites etc.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

15.7.2 Construction Plant Facilities

The Contractor will require work areas for various functions including space for stockpiling aggregates, aggregate manufacturing, and concrete batching and mixing plants.

Aggregate Processing System

The Aggregate Processing System for preparation of coarse and fine aggregates is proposed at the Powerhouse site due to easy access and the availability of wide area of land. The estimated requirement of aggregates of different sizes is 63,790 m^3. In accordance with the demand of finished aggregates, consideration of the losses during transportation, processing and pouring and counting the non-uniform coefficient of production, the system's overall raw material processing capacity is assumed to be 50 m^3/h.

The Aggregate Processing System mainly consists of raw material stock yard, coarse screening plant, pre-screening plant, coarse crushing plant, storage area for the semi-finished products, intermediate crushing plant, main screening plant, fine crushing plant, sand making plant, storage area for the finished product, water processing system, power supply system and belt conveyor system, etc. Aggregate processing system shall adopt the three-stage crushing and closed production workmanship. Main equipment includes jaw crusher, cone crusher, vertical shaft impact crusher, vibrating feeder, vibrating screen classifier, screw sand washer, etc.

15.7.2.1 Concrete Production System

The estimated total quantity of concrete in this project is about 73,600 m^3. Two independent units are proposed to meet the requirement of concrete and shotcrete for the Project structures. One concrete mixing batching plant of 30 m^3/hr capacity is proposed on left bank side, downstream of the Weir site to cater for the needs of Main Weir, Undersluice / flushing channel, Power Intake and Access Tunnel / Adit to Headrace Tunnel near Power Intake.

Another Concrete Batch of 60 m^3/hr capacity is planned to be install at Powerhouse site as suitable area is available here. This batch plant will cater for the needs of Headrace Tunnel, Surge Tank, Powerhouse, Tailrace Channel, Access tunnel / Adit to Headrace Tunnel near Surge Tank. The Temporary roads may be constructed to transport concrete at desired site location from these batch plants.

Concrete system consists of automobile receiver bin, finished charging bucket, belt conveyor, concrete mixing plant, screw conveyer, cementing material tank, air compressor room, cooling system etc. This facility need not be on level ground and it can be installed on a series of cut benches with delivery access with bins, cooling system, batch and mix plant possibly on three separate levels.

15.7.3 Other Site Facilities

The other site facilities that will be required by the Contractor for the construction of ALHPP are described below. Most of these facilities are planned near Powerhouse site where suitable wide land is available.

- Materials Laboratory equipped with the equipment for test on soil, rock, concrete, aggregates, bricks, embankment materials and filter materials.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Temporary facilities / buildings such as steelwork and carpenter's workshops, mechanical equipment repairing workshop, fabrication workshop, storage yards for storing equipment, machinery, aggregate, sand, cement, steel reinforcement, scaffolding, bricks, chemicals, explosives to be used during blasting operations and fuel tanks etc.

- Temporary roads connecting camp & other temporary facilities with the sites of main structures in the project area, other than the access roads.

- Religious facilities within the camp areas for performing religious activities.

- Health facilities including portable First Aid Station equipped to provide primary care for emergencies relating to injuries, burns, broken bones etc. Arrangements shall be made with the closest major hospital to cater for accident and hospitalization cases.

- Emergency fire protection facilities in all offices and buildings to cater for any fire hazard including hose, fire extinguishers, pails and shovels etc.

- Wireless communication system for communication between site personnel, site offices and the working areas.

- Security facilities including security check posts at main entrance of camp/site. All the work areas, storage areas and such other area where construction activity is proceeding shall be guarded by the security guards and watchmen for security.

Spares and standby equipment to ensure continuity and proper completion of operations, including diesel power generating sets, earthwork plant, concrete mixing and transportation plant, grouting equipment, dewatering plant and other key plant and equipment required to ensure work progress.

15.7.4 Residential Colony

Residential accommodation for the Project Executing Agency and Consultant's staff is also an important requirement, which must be made available prior to the start of the main works. The construction of Residential Colony will be started simultaneously with the construction of access roads.
An area of 2.5 Acres will be required for the construction of office, residential block for O&M Staff including Engineers, supervisory and lower staff, rest house, mosque, basic health unit, shops and other allied services including roads, water supply / sewage disposal system and the electricity arrangement etc. The Colony once completed will be utilized for the management personnel of the Employer and Consultant till the project construction completes, to facilitate the communication and management. After the completion of the project the colony will be utilized by Operation & Maintenance (O&M) staff.

Area for both the Residential Colony & Contractor's Camp are planned at one place near Powerhouse Site as a wide area of land is available here and also other plants / workshops are to be installed here.

15.7.5 Access Roads to Main Work Sites

Access road is the most important structure to effectively start the construction activities; therefore, the construction of access roads to the Project structure's sites shall be taken up immediately after the mobilization of Contractor at Project site.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

From transportation tunnel - 1 inlet of existing KKH, a stretch of old KKH first slopes down from El. 2400 masl to El. 2360 masl and then slopes up to El. 2500 masl with few sharp turns to approach existing spillway of Attabad lake. This stretch of old KKH within the Project Area will be improved / upgraded to provide access to the various Project structures and to serve as carriage for material and equipment required for the Project structures.

From El. 2360 masl, the old KKH path branch off to a track which slopes down to El. 2310 to approach Sarat and Salmanabad Villages through a bridge on Hunza River near proposed Powerhouse site. The track will be improved alongwith the construction of access roads to approach Powerhouse, Residential Colony, Construction camp and utilities to be established. Another track branch off from old KKH which slopes down from El. 2480 masl to El. 2420 masl near existing spillway. This track was developed at the time of creation of existing spillway of Attabad Lake and requires improvement to access Weir and Power Intake sites.

Besides the improvement / upgradation of old KKH and tracks, the access roads to access tunnels / adits for Headrace Tunnel and Surge Tank will also require to be constructed.

15.7.6 Additional Survey & Investigations

Based on review of existing survey and investigations, the requirements for additional field investigations will be identified by EPC Contractor and then be carried out as required for Detailed Engineering Design by the EPC Contractor.

15.7.7 Detailed Engineering Design

The EPC Contractor will be responsible for the Detailed Engineering Design and will be approved by Project Consultants engaged for construction supervision. Its objective is to achieve an effective design to enable the construction of hydropower plant that meets Project requirements for safety, availability & operability / maintainability with no adverse environmental impact and within the agreed cost and schedule. The EPC Contractor will design all Permanent works and all necessary Temporary works.

The design of access roads, Contractor’s camp & related facilities, Civil and E&M design of all the Project components will be commenced in parallel with the preparatory works. The design of access roads, Contractor’s camp & related facilities will be completed within one month for early construction of access road and Contractor camp & facilities. However, detailed Civil and E&M design of the Project will be presented by the EPC Contractor step by step for later work execution.

15.8 CONSTRUCTION PLANNING AND METHODOLOGY

The ALHPP involves execution of considerable quantities of excavation and concreting for structures. Considering the magnitude and nature of construction activities, mechanized construction has been considered for all type of construction job so as to achieve consistent quality at a faster rate for timely completion of the Project.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The Project involves overflow weir, sediment flushing channel / undersluice, power intake, low pressure headrace tunnel, surge tank, penstock, powerhouse and tailrace channel. The location arrangement and structural details of the above components are shown in Volume-5 (Drawings). The work on all these components can be carried out simultaneously.

The construction of low pressure headrace tunnel is very significant item in order to have early completion of the ALHPP. Diversion works are mandatory for the commencement of the works on sediment flushing channel and overflow weir. The construction of the access tunnels to the headrace tunnel near power intake and surge tank areas will help to make an early start on excavation of headrace tunnel which lies on the critical path. Rock mechanics tests of tunnel and surge tank will also help in determining the kind of support system required in the crowns and walls of these underground structures. Timely rock geology identification will facilitate in design, procurement and manufacturing of support systems and will help in timely completion of the Project.

The construction methodology described in this section of Feasibility Report show techniques for main structural units of ALHPP and is based on the assumption that the construction work will be executed by an experienced EPC Contractor selected through competitive bidding, who will be fully capable of employing modern construction methods, managing proper / sufficient manpower and equipment for timely completion of the Project. However, these construction methods should not restrict the EPC Contractor using other acceptable approaches and methods to achieve desired quantity & quality of works in scheduled time and cost.

15.8.1 Care and Handling of Water

It is envisaged that two temporary coffer dams will be constructed in 02 stages. Stockpiling of adequate material and mobilization of suitable equipment will be made well in time before the construction of coffer dams. The construction of Stage-I coffer dam at upstream of sediment flushing channel / undersluice with crest level at El. 2422 masl, will be initiated as soon as possible after the improvement / upgrading the access path to Weir Site. On the completion of the Stage-I coffer dam, the excavation of sediment flushing channel / undersluice will be commenced and the Hunza River / Attabad Lake water will continue flowing through the existing spillway.

The construction of Stage-II coffer dam at upstream of overflow weir section with crest level at El. 2422 masl, will be initiated after the completion of works of sediment flushing channel / undersluice. On the completion of Stage-II coffer dam, the Hunza River / Attabad Lake water will be diverted through sediment flushing channel. The Stage-II coffer dam is envisaged to prevent entry of water into the working area for construction of overflow weir in dry portion.

15.8.2 Sediment Flushing Channel / Undersluice

The suspended sediments transported by Hunza River and entering the power intake will unavoidably result in a certain wear and tear. The extent of the abrasion depends largely on the concentration, size and mineralogical characteristics of the sediment particles on one hand and the turbine type and runner speed on the other. This abrasion and the resulting need for overhaul and replacement of runners cannot be avoided; however, the frequency of repair works can be reduced by arrangement of flushing facilities.

For this purpose, the sediment flushing channel will be constructed at the left side of overflow weir section, consisting of low level outlets with gated arrangement (three bays each having 05

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

m width) and during construction of overflow weir will be used as diversion channel. The invert level of sediment flushing / undersluice section is planned at El. 2402 masl.

The sediment flushing channel would be founded on overburden / slided mass. The excavation work of sediment flushing channel will begin after the slope stabilization of left bank slopes. During its excavation, water will be diverted through existing spillway. Upon the completion of coffer dam (Stage-I), the sediment flushing channel will be excavated below its planned invert level. The occurrence of large size boulders within the sediment flushing channel area must be anticipated by the Contractor, for which proper methodology needs to be applied for removal of such boulders.

During the excavation, high moisture content materials can be encountered. The Contractor must ensure that his excavation methods ensure for the additional and unseen difficulties associated with removing this material, such as efficient transport of high moisture content material and complex care of water issues. The excavated material will be disposed-off at spoil areas planned near the Powerhouse site.

After the completion of excavation, vertical concrete cut off walls upto the required depth will be provided on upstream and downstream edge of sediment flushing section, followed by the concrete works of channel. Concrete will be poured up to the invert level, at which point where gate will be rested. Concrete placements will be temporarily diverted to flushing channel, until the completion of grouting and drainage curtain works in each bay. When the concrete works have been sufficiently progressed, the gate guides will be installed, aligned, and measured for tolerance. When the survey of these guides will confirm their position, second stage concrete will be placed. It is anticipated that the radial gates will be fabricated offsite in manageable sections. A test assembly of the gates would be undertaken at the fabrication yard, following which the gates would be dismantled to their transportable sections for mobilization to site.

At site, the gates would be preassembled into larger sections, such as trunnion arms and full height skin plate sections. These gate components would then be hoisted into place and fixed into final position. The exact process for undertaken this complex task would need to be developed in detail by the Contractor, in collaboration with the gate supplier. Once the flushing section gates are installed, the remainder of the M&E equipment i.e. gate hoists would be installed. Stop logs would also be fabricated and brought to site in full width segments. Dry commissioning of both the radial gates and stop logs would occur. Wet commissioning will follow when an appropriate level of lake is reached.

The stone apron will provided at the upstream side. Before placing stone apron, the ground will be properly adjusted and compacted and if required covered by a filter fabric. The sediment flushing channel is envisaged to be completed in 8 months period.

Upon the completion of sediment flushing channel, lake water will be diverted through this structure, to commence construction activities on power intake and overflow weir section.

15.8.3 Power Intake

A two bay intake structure shall be constructed on left bank of Attabad Lake upstream of main weir for passing the design discharge. The Intake level will be 4m above the invert level of sediment flushing channel section to keep the area upstream of the intake sediment free. It shall be equipped with a trashrack to prevent intrusion of debris (like timber, leaves, trees etc.)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

into the waterways and with a hydraulically operated gate for emergency closure and for isolating the waterways for inspection and maintenance.

After the completion of sediment flushing channel in all respects and drawdown of water level in Lake below El. 2400 masl, the construction work on intake structure will commence. The excavation of intake has to be made at El. 2404 masl. To access the power intake area, access road has to be constructed first and after the construction of intake structure, it will be removed. Concrete and other materials will be brought to the structure via the same route.

The excavation for the power intake shall be open cut rock excavation and will be done from top to bottom. The slope protection and support measures will be installed after each excavation step and prior to the next excavation step. The excavation will be done in a manner that the remaining rock slopes are not damaged, rock properties are maintained and rock is not loosened. The rock strengths shall be maintained by using adequate blasting techniques. The excavation beyond the theoretical rock contour shall be backfilled with concrete or shotcrete.

After completion of excavation works at intake, the erection of formwork of suitable length for pouring concrete will be done with concrete pumps to expedite the work. The excavation and concreting activities at intake structure are envisaged to be completed in 12 months period. After the completion of intake structure, a trashrack cleaning machine (TRCM) will be installed for removal of debris infront of trashracks. A gantry will be installed for placement and removal of the stoplogs.

15.8.4 Overflow Weir / Ungated Spillway

The overflow weir is a concrete gravity type, un-gated section (60 m wide) with downstream stilling basin. The weir would be founded on overburden / slided mass. The weir crest (El. 2414 masl) will be of ogee type which will transfer the water from Attabad Lake reservoir in a smooth decline to the downstream. A stilling basin downstream of weir will dissipate the energy by creating a hydraulic jump and shall prevent downstream erosion.

Once the construction of coffer dam (stage-II) will be completed, the work on the overflow weir section will be commenced with its excavation to required level with excavators. The occurrence of large size boulders within the main weir area must be anticipated by the Contractor, for which proper methodology needs to be applied for removal of such boulders.

During the excavation of overflow weir section, high moisture content materials can be encountered. The Contractor must ensure that his excavation methods ensure for the additional and unseen difficulties associated with removing this material, such as efficient transport of high moisture content material and complex care of water issues. The muck generated from the excavation of main weir will be disposed-off along right bank downstream of the weir site

After the completion of excavation, vertical concrete cut off walls upto the required depth will be provided on upstream edge and center of weir.

For overflow portion, the crest of the weir will be 2412.0 masl and downstream basin at El. 2400.10 masl. After completion of the excavation up to the required level, the construction of weir will be commenced in form of monoliths by erecting formwork. The concrete hauling trucks with vibrating drum will be used for pouring concrete. The specified strength of concrete in lifts usually one meter in height will be poured into formwork of the various monoliths. After pouring

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

the concrete, chipping or green cutting with water and air pressure on the top of the laid concrete lift will be carried out for preparation of a proper bond required for placing the next lift of the concreting. PVC water-stop will be provided between the two monoliths at u/s of contraction joints to stop the seepage, if any. In this way, concreting up to the crest level 2412.0 masl will be completed.

The stone apron will be provided at the upstream and downstream side. Before placing stone apron, the ground will be properly adjusted and compacted and if required covered by a filter fabric. The overflow weir is envisaged to be completed in 9-month period. Upon completion of overflow weir, the working area will be re-flooded to match the lake water level.

15.8.5 Access Tunnels / Adits for Headrace Tunnel

The biggest portion of the underground works is the excavation of the headrace tunnel, which is approximately 2.3 km long. The headrace tunnel covers about 95% of the total underground works excavation volume. Since the main objective of the project planning is time and cost minimization, the total of these works have to be split up into reasonable portions to enable simultaneous work at several sections. In accordance with the study of local geographical and environmental conditions, the provision of 02 access tunnels has been proposed. Nevertheless, the tunneling will remain the critical path for the civil works. The following access tunnels will be constructed to access the headrace tunnel:

Access Tunnel Adit	Length
Near Power Intake	450 m
Near Surge Tank	202 m

The excavation of these access tunnels will be done using the drill and blast technique as explained below for the low pressure headrace tunnel.

15.8.6 Low Pressure Headrace Tunnel

From power intake, approximately 2,300 m long low pressure headrace tunnel (horseshoe shape), having 5.5 m width & 5.5 m height would run along the left bank of Hunza River leading to surge tank. The upstream level of tunnel is El. 2,402.5 masl whereas downstream level is El. 2,385 masl.

After the completion of access tunnels / adits, the underground works for the headrace tunnel will be commenced immediately because the construction of headrace tunnel is connected with the dependent works of surge tank structure. Taking into account the geological and execution conditions, the “Drill and Blast method” is proposed for the excavation of the headrace tunnel. The underground works of headrace tunnel are assumed to be the most critical part of the Project.

The headrace tunnel will be sub-divided into two sections. With this division in construction sections, it will be possible to work simultaneously at two fronts basically independently from each other. However, due to limitations of space for spoil areas near the power intake site, major excavation will be executed through the section near surge tank for disposal of muck at spoil areas near Powerhouse site. Accordingly, the headrace section # 01 will be from its start

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

at power intake upto about 700 m length. The headrace section # 02 will be from 700 m to 2300 m (1600 m long)

The surface geological mapping of the tunnel area has been carried out. A good to poor quality rocks are present in headrace tunnel area. The tunnel length for each rock classification and its quantity are used for tunnel progress rate calculation & for establishing the tunnel scheduling.

The headrace tunnel will be constructed in three main phases; the top heading, benching and invert. The drill and blast method using a jumbo drill will be used for the top heading excavation, and the front-end loaders and articulated trucks for mucking out the excavated material. The benching will be carried out by drilling a pattern of vertical charge holes through the floor of the top heading. The holes will be charged and shot as the excavation of the bench proceeds. The rock shot will be removed with front end loaders and trucks. Similarly, invert will be excavated at the end of tunnel excavation.

Depending on the type of rock, the advance rate for the top headings is assumed as 2 to 3 m per day based on two 10-hour shifts. This advance rate is adopted after reviewing data derived from standard guides as well as ongoing projects of similar nature within Pakistan, and is used for establishing the tunnel scheduling. It has been estimated that the excavation of tunnel will be carried out in 533 days.

Support measures comprising rock bolts, shotcrete, wire mesh, steel sets and drainage holes will be adopted depending on the condition of the rock strata. After completing the excavation and temporary supports in whole length of headrace tunnel, the erection of steel sliding forms of suitable length will be applied for pouring concrete with concrete pumps to expedite the concrete lining. A standard progress assumes at 120 m/month for arch and wall applying steel sliding form and 500 m/month for inverts. The backfill grout will follow the concrete lining.

After the completion of construction activities of headrace tunnel, the access tunnels/adits will be plug with the concrete. Total time of around 25 months has been estimated for the excavation, rock support measures and concrete lining of headrace tunnel.

15.8.7 Surge Tank

A circular surge tank having 10 m diameter and 45 m high will be constructed at the intersection of the headrace tunnel and penstock to prevent the adverse effect of water hammer pressure or flow variation due to turbine load fluctuation on the headrace and other structures.

For approaching surge tank, an access road and access tunnel / adit will be constructed upto its crown. The construction of access road will be commenced simultaneously with the other access roads to the work sites. The excavation work for access tunnel will be started from its outlet and mucking of excavated material will also be done from the same end. Rock bolting and shotcreting on excavated faces of access tunnel shall be done depending on the condition of the rock strata.

The work for surge tank will be done more or less independently from the other works. Dependence exists to the construction of 2nd section of the headrace tunnel because it will be used for mucking of excavated material from the surge tank structure.

After the completion of access tunnel / adit, the manpower and equipment shall be mobilized and downward excavation shall be done by raise boring to the full diameter of the surge tank.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Prior to raise boring activities, the excavation will be done to prepare the staging area and platform for the surge tank. Once the boring machine is set, drilling of pilot hole will commence. Drilling of pilot hole will be done until breakthrough with the tank bottom at headrace tunnel. After breakthrough, widening the pilot hole by raise boring will be done. The spoil generated shall be mucked out from the tank bottom off the headrace tunnel using wheeled loader that will load the spoil to dump trucks for transport to spoil areas near powerhouse site. Upon completion of raise bore, the boring equipment will be dismantled and removed from the site.

The raise bore will then be widened to the full diameter of the tank. After initial excavation, collaring of the tank will be done by applying the support measures. Suitable hoisting equipment and related accessories will be installed to transport equipment, supplies and personnel from the tank collar to the work area. After advancing downwards, the sinking platform will be installed to facilitate the work of the tank construction.

Main excavation will be by drill and blast method, starting from the top and progressing downward. The explosives charge will be limited to ensure that the pilot raise bore is not deteriorated or damaged by the blasting operations. After each blast, spoil will be dropped to the tank bottom through the pilot raise bore which shall then be loaded by a wheeled loader into dump trucks that will transport the spoil to the spoil area through the access tunnel / adit to headrace tunnel near surge tank.

After completion of excavation, the concrete lining in this structure will be taken up immediately by starting from its bottom to top with slip forms moving in an upward direction towards the tank collar. A total of 12 months have been allocated for completion of the underground excavation and concrete works of the surge tank.

15.8.8 Penstock

A Penstock of 3.6 m dia will be laid under the left bank slopes for conveying water from headrace tunnel to 03 Vertical Shaft Francis Turbines to be housed in Powerhouse. At the end, the penstock shall be trifurcated into penstock manifolds with reduced dia. In the first section upto 80 m, the penstock will cross horizontally the rock starting from the bottom of surge tank. This section can be considered as an extension of headrace tunnel, lined with an embedded steel lining. The second section, 455 m long will be the embedded penstock descending towards the powerhouse.

For the excavation of first section, the similar method of excavation as for headrace tunnel i.e. drill and blast method will be applied. For the second section, the alluvium will be excavated upto the required depth over which concrete will be placed for penstock to be laid. Excavation from the penstock trench will be stockpiled in the area near to the powerhouse site.

The penstock steel liner will be manufactured in the workshop at the Project site from the steel plates and welded into 4 to 6 m long sections, which after testing will be transported to their places of installation using trailers. The installation of penstock will be started from the upstream side moving downwards towards the powerhouse. The penstock will be placed on a bedding of blinding concrete. After laying in final position, the penstock sections will be welded, followed by the concreting of 8 no. anchor blocks and backfilling. The construction of penstock will be taken up alongwith the powerhouse construction. Total time envisaged for the construction of penstock is 10 months.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

15.8.9 Powerhouse Civil Works

The Powerhouse is proposed 63 m long, 20 m wide and 35 m high with four floors at different levels. Machine Hall floor would be at El. 2306.2 masl and powerhouse top shall be at El.2314.5 masl. The main hall would accommodate three vertical Francis units, each of 18 MW, alongwith generators, switch cabinets, trifurcation of penstock pipe and erection bay.

The construction of powerhouse structure will be taken up independently after the construction of access road to powerhouse site. The powerhouse will be excavated upto the lowest El 2292 masl of the powerhouse pit. The muck generated from the excavation will be disposed off at the spoil areas near powerhouse site.

Upon completion of powerhouse excavation, the steel reinforced base concrete will be poured and subsequent concrete works for sub-structure and super-structure of powerhouse will be commenced in accordance with the planned sequence. The sloping trussed roof will be constructed along with the installation of powerhouse crane. Backfilling around powerhouse will be done upon the completion of powerhouse substructure. All these activities related to powerhouse construction will be completed in 15.5 months. The powerhouse architectural works will be completed parallel to testing and commissioning of units.

15.8.10 Unit Erection

The three generating units will be housed in the powerhouse, with the operating floor at El. 2,306.2 masl. A large erection bay is provided to maximize the ability to work on multiple units at a time to save time. Each turbine is connected via a main inlet valve to a steel penstock.

It is intended that the EPC Contractor will have three complete teams of workers on site, enabling the erection of three units in parallel. In addition, the workforce will be divided so that a team that installs and welds embedded components, such as the draft tube and spiral casing, will be separate from a team that installs the rotating plant (head cover, guide vanes etc.). There will also be separate generator teams, able to work on stators and rotors in parallel. The main inlet valves (MIV) for 03 turbines will be installed for commissioning of units when headrace tunnel is watered.

In draft tube construction, civil and mechanical teams will work continuously without impeding the each other. Once the draft tube liner has been installed for a particular unit, the mechanical team will move on to the next unit while the civil team undertakes draft tube embedment. Once the next draft tube liner is installed, and the concrete of the current unit is sufficiently cured, the team will move back to the initial unit to install and weld the spiral casing, and so on. In this way the mechanical and civil teams will be continuously employed without hindering each other.

15.8.11 Mechanical & Electrical Installations

The installation of the mechanical and electrical equipment can be broken down into the following major stages, excluding the civil works that are required to support these works, such as pouring the floor columns, beams, floors and plinths:

- Installation and embedment of the turbine embedded parts, comprising the draft tube liner, spiral casing, stay ring, and turbine pit liner.

- Installation and alignment of the turbine and covers to the stage where work can commence on the generators such as head cover, regulating ring, servomotors, runner

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

and turbine shaft. These items are large and heavy and need to be lowered into the turbine pit using the powerhouse crane, and hence no work in the generator enclosure can take place before these works are complete.

- Installation of the generator lower bracket (which is then covered over and used as a working platform) to allow generator stator building in parallel with installation of the remaining turbine components, which will need to be taken into the turbine pit via the pit entrance on the turbine floor.

- Installation of 03 spherical Main Inlet Valves (MIV). Each valve will be taken to its plinth and aligned with the penstock stub and spiral inlet, a potentially time consuming process depending on the accuracy of alignment of those components. The upstream stub pipe of the MIV will be welded to the penstock manifold stub. A stub piece will be welded to the spiral end, and the remaining gap filled with an adjustable make-up ring. The servomotor(s) will be installed as well as control pipework and fittings to enable the valve to be dry commissioned.

- Generator stator building. The stator frame will be brought to the erection bay in three sections. They can then either be assembled on the erection bay and taken as one assembly to the generator enclosure or taken as separate items and assembled in the enclosure. The method used would be that preferred by the manufacturer. Once in position and aligned the stator core will be built. The core will consist of layers of punched magnetic sheets of steel lowered over retaining rods to form a complete ring with no vertical joints. The layers will be built up and clamped to predetermined pressures at a number of stages to ensure the build is progressing satisfactorily. Care will be required to ensure the stator core is completely circular. Resistance temperature detectors will be embedded within the core to provide temperature information during unit operation. Once the core layers are complete the competed core will be clamped to ensure it does not move during operation. Upon tests to ensure the core is satisfactory, the stator winding will commence. There will be two layers of windings in each slot, but the exact dimensions and construction arrangements will be to the manufacturer’s standard design.

- Generator rotor building. This work will be undertaken on the erection bay and as such can take place in parallel with the stator building. The rotor spider (the frame upon which the rotor pole rim is mounted) will be of forged construction and brought into the powerhouse as one item. It will be lowered over the generator shaft, and then the rim and brake track will be fitted, followed by the rotor poles.

- The upper bracket, bearings and slip-rings will be installed once the fully assembled and tested rotor has been lowered into the generator onto the thrust bearing (which will be mounted on the lower bracket). The rotor will be the heaviest single item to be lifted within a powerhouse, and will require two overhead cranes to operate in tandem (i.e. controlled as a single device) using a specially designed lifting beam.

- The generator transformers will be installed in transformer bays outside powerhouse at its back. During the erection stage, the transformers will be delivered directly to the transformer bays. The transformers will be delivered as complete tanks (that is, the core will be installed in the tank and the assembly sealed), but the internal voids will be filled with nitrogen rather than oil and most other items will be sent separately (such as the

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

conservator) to reduce transportation weight. The transformers will have to be drained on the nitrogen, fitted out with all the remaining components and then filled with oil and tested. Upon completion of generating units, the transformers will be connected to Insulated Bus Pipes (IPBs) and HV switchgear for on-line commissioning.

- Main electrical equipment comprising excitation system, control boards, isolated phase busbars, gas insulated busbars (GIB) and the switchyard electrical equipment. All these items can be installed as civil works are finished and time allows.

- The turbine and generator auxiliary systems, comprising the cooling water system, lubrication system, compressed air system, braking and jacking system, shaft seal system, drainage and dewatering system and others can be installed in parallel with the main installation works, timed to finish at the same time.

- Lighting and small power equipment will need to be installed on a unit basis to provide the required amenities for the station operations and maintenance personnel once each unit is commissioned.

The total time for excavation, concreting in powerhouse and installation of vertical Francis turbines, generators, transformers and auxiliary systems is estimated to be 21 months.

15.8.12 Tailrace Channel

The draft tube of each turbine unit will drain water in the 20 m long tailrace channel and it finally will be discharged into Hunza river. The tail water level is therefore maintained to retain the minimum setting for turbines. The excavation of tailrace channel can be started and completed independent of the other activities in parallel with the excavation of Powerhouse starts.

15.8.13 Switchyard

A surface 132 kV switchyard will be located near Powerhouse. The civil works of the switchyard area will be started after the construction of powerhouse superstructure. The switchyard equipment will be transported to its location through access road to Powerhouse. The erection of switchyard equipment will be done using the 5 ton mobile crane. Cabling for instrumentation, monitoring and controls alongwith cable terminations will be completed before the start of unit testing. It is envisaged that the construction and installation of the equipment in switchyard will take 07 months.

15.8.14 Transmission Lines

The two double circuit 132 kV transmission line will be erected, each between ALHPP and grid station at Aliabad (70 km) and Sost (27 km) for transfer of power generated at Attabad to the local grids. The construction of transmission lines is critical for commissioning and commercial operation of the powerhouse units. This activity can proceed independently and does not have any link with the other project construction activities. But it is important that transmission line construction should be planned in such a way that at least one circuit must be available before commissioning of first generating unit, so that the energy generated can be transmitted to the local grid.

The construction activities include construction of foundations, fixing of towers, installation of equipment, stringing, etc., and other activities include transportation of construction materials and equipment. It is estimated that construction of transmission lines will take 23 months.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Another significant aspect for on time completion of the transmission lines is the marking of route corridors and acquisition of land prior to commencement of the construction activities.

Diligent planning will be required to complete the geotechnical and other investigations, route alignment, acquisition of right of way, identification of access road routes and crossings over the Hunza River etc., before the actual start of construction of the transmission lines.

15.8.15 Transportation, Assembly of Electro-Mechanical Equipment

All the Electrical & Mechanical equipment, which includes main inlet valve, turbine and generator parts, transformers, gate equipment, HV & LV switchgear, crane and other auxiliaries, will be transported from port to site on trailers and containers via National highway / Motorway and KKH. The largest pieces of equipment will be transported to site in parts and will be assembled at site. This equipment will be stored at site in the work yards / storage areas, with sensitive parts stored in covered areas for protection against rain, dust and weather action.

The first item of equipment to be installed in the powerhouse is the crane, for which the EPC Contractor will complete the civil works in erection bay and complete the erection of crane rails. The crane will be tested for travelling and carrying of the designed load with all protections in place, after completing installations of all parts.

15.8.16 Testing and Commissioning

After installation of all electro-mechanical equipment, two months will be required for testing and commissioning of the installed equipment before the start of commercial operation.

15.9 PROJECT IMPLEMENTATION SCHEDULE

The proposed implementation schedule takes account of the preliminary design of each structure and facilities, work quantities and site conditions. It is prepared on the basis of the construction plan, estimated construction progress, rate of each activity and work sequence. The Project Implementation Schedule spans over a period of 50 months, which includes 36 months for construction activities and 14 months for pre-construction activities. It is anticipated that the construction of the entire project shall be completed within this time frame. The Project Implementation Schedule is presented as Annexure-A.

During detailed design and execution of actual works, EPC Contractor may develop his own schedule in such a way that most of the work can be taken up simultaneously on various project components in order to complete the project in the shortest possible time.

15.10 CONSTRUCTION MANAGEMENT

15.10.1 Project Executing Agency

Pakistan Water and Power Development Authority (WAPDA) will execute the Project as Project Executing Agency. WAPDA in close liaison with the Consultants will provide supervision of all the Project works by EPC Contractor and will facilitate all staff permits, authorizations, licenses, customs clearance of imported equipment, materials & personal effects required for the execution of the Project. WAPDA will also coordinate with Gilgit Baltistan's authorities and departments for any issues arising about the project, which require resolution by inter-departmental interaction.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

15.10.2 Consultants

The supervision of construction activities by EPC Contractor will be carried out by independent Consultants, comprised of a Joint Venture of local and international engineering firms with proven track records on such projects. The Consultants will be reporting to the Project Executing Authority.

During the Pre-Construction phase, the Consultants will prepare EPC Tender Documents of the Project. After approval of the Tender Documents, the Consultants will assist Project Executing Agency in the procurement of EPC Contractor.

During the Construction Phase of the Project, the Consultants will in general review & monitor the detailed design, construction, manufacturing, procurement, installation, commissioning & testing of works by the EPC Contractor. The Consultant's services will be in close coordination with the Project Executing Agency. The Consultant's major tasks for EPC implementation of the Project will be:

- To monitor additional field investigations, review of procedures adopted and types of tests performed by the Contractor.
- To examine the basis of design by the Contractor and review of design reports, detailed construction drawings, specifications, construction schedules, quality assurance / quality control manuals and health, safety & environmental manuals by the Contractor.
- To monitor the manufacturing and procurement of equipment by the Contractor for timely delivery and supervision of all quality control tests at manufacturer's workshops.
- To monitor Contractor's progress of work and coordination of construction activities of various civil and E&M works to ensure execution of the project within time and according to applicable standards.
- To monitor Contractor's compliance with construction management & environmental management plans.
- To verify the works executed by the Contractor for the purposes of making interim payments and the final payment.
- To review variations and claims by the Contractor and provide assistance to Project Executing Agency in processing the claims.
- To review Contractor's As-Built documentation / drawings, operation & maintenance manuals and project completion reports.

16 ENVIRONOMENTAL IMPACT ASSESSMENT

16.1 GENERAL

Administratively, the Gilgit-Baltistan (Gilgit-Baltistan) is divided into 10 districts: Gilgit, Ghizer, Hunza, Nagar, Skardu, Ghanche, Shigar, Kharmang, Diamer and Astore. Previously there were seven districts in the Region. In 2016, the number of districts increased from seven to ten after the addition of 2 districts in Baltistan Region and the bifurcation of the Hunza-Nagar to 2 districts. in 2021, there are 10 districts in the entire region, 4 in the Baltistan Division, 4 in the Gilgit Division and two in the Diamer Division. In 2019, Darel, Tangir, GupisYasin and Roundu has been announced as new districts by the Gilgit-Baltistan Cabinet, but so far these are not notified officially

Figure 16-1 District and Tehsil Boundaries of Gilgit-Baltistan

Hunza Valley was composed of two independent kingdoms: Hunza and Nagar in the early 1600s. Hunza is located on the branch of the ancient Silk Route from Kashgar to Kashmir and is linked to Turkistan/western China since ancient times.

Attabad Lake was created due to a massive land slide in January, 2010. Water and Power Department (W&P Dept.) of Gilgit-Baltistan intends to utilize this storage as an opportunity to develop Hydropower Project of appropriate capacity utilizing this potential in order to meet the ever increasing demand of Hunza District and its suburbs.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.2 ENVIRONMENTAL AND SOCIAL IMPACT ASSESSMENT (ESIA)

The ESIA is the planning tool developed in recent years to foresee the environmental and social impacts of human intervention in nature arising from development projects. Major hydropower and storage dam projects invariably result in many far-reaching environmental, ecological and socio-cultural changes. Some of these changes benefit human population, while others threaten the natural resource base on a short or long term basis.

The negative environmental and social impacts of a development project are avoided or minimized through the ESIA and where adverse impacts cannot be avoided, the mitigation measures and resettlement activities are conceived and executed as part of the project.

The overall objectives of an ESIA in accordance with the Pakistan Environment Protection Act (PEPA 1997), and the World Bank guidelines (OP 4.0) include the following:

- Help to ensure the environmental and social soundness and sustainability of projects.
- Support integration of environmental and social aspects of projects into the decision making process.
- Promote environmentally sustainable development by supporting the protection, conservation, maintenance, and rehabilitation of natural habitats and their functions.
- Avoid or minimize involuntary resettlement and if not feasible, to assist displaced persons in improving or at least restoring their livelihoods and standards of living in real terms relative to pre-displacement levels or to levels prevailing prior to the beginning of project implementation, whichever is higher.
- Design and implement projects in a way that fosters full respect for indigenous peoples' dignity, human rights, and cultural uniqueness and so that they: (a) receive culturally compatible social and economic benefits; and (b) do not suffer adverse effects during the development process.
- Assist in preserving physical cultural resources and avoiding their destruction or damage.
- Assure quality, health and safety in the design and construction of new dams and the rehabilitation of existing dams, and in carrying out activities that may be affected by an existing dam.
- Enable vulnerable and disadvantaged stakeholder groups to participate in an informed manner.

16.3 PROJECT CATEGORIZATION

According to Pakistan Environment Protection Agency (PEPA) regulations for review of IEE and EIA, hydroelectric projects with a generation capacity of over 50 MW and power transmission lines with a capacity more than 11 kV fall into Schedule-II, i.e. projects requiring EIA. Similarly, in accordance with the guidelines of the World Bank, the Asian Development Bank and the Japan Bank for International Cooperation Environmental guidelines, the AALHPP (with a planned generating capacity of 54 MW and 132 kV power transmission lines) would fall within the category 'A' projects could be having significant impacts on the environment and requiring a full scale EIA.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.4 SCOPE AND LIMITATIONS OF ESIA

16.4.1 Scope

The scope of the study includes this ESIA which only covers the dam site, reservoir, powerhouse areas and transmission systems. Resettlement Action Plan (RAP) is not under consideration as there is no displacement of people involved. Team of Engineers from Hydro Planning Organization (HPO) have envisaged the following statement of work related to environmental studies:

a. Review of national and local guidelines, laws and policies;

b. Review of all relevant existing data, studies, reports and drawings;

c. Avoid, minimize, mitigate and the potential significant environmental and social impacts due to the proposed intervention;

d. Collection of baseline data related to physical, ecological and social environmental aspects;

e. Identification, evaluation and categorization of the potentially significant adverse physical, ecological and socio-economic impacts on the local environment during the construction and operational stages of the proposed Hydropower Project;

f. Recommend appropriate environmental and social mitigation measures for the identified adverse impacts and monitoring plans to address them;

g. Preparation of Environment Monitoring Management Plan (EMMP);

h. Cost estimate for environmental setup;

i. Public consultation and disclosure;

16.4.2 Limitations

The baseline information documented in the present report reflects the prevailing physical, biological and socio-economic conditions of the Project Area. The Project is at Feasibility Stage and the detailed design and tender documents preparation stages will follow during the execution. If the Project is implemented after two years of completion of the Feasibility Stage then certain variables such as development of infrastructure, population growth, increase or decrease in the forest, land use, cropping patterns and economic conditions could be changed significantly.

16.5 APPROACH AND METHODOLOGY

16.5.1 Review of Previous Studies

ALHPP was conceived by W&P. Dept. of Gilgit-Baltistan. Consequently, a Feasibility Study was conducted by the W&P. Dept. of Gilgit-Baltistan through Consultants with a designed capacity of Project for 32.5 MW. Therefore, only IEE was carried out to fulfill the requirement of the PEPA by the consultants engaged by govt. of GILGIT-BALTISTAN because ESIA was not required for projects less than 50 MW. Later on the request of govt. of Gilgit-Baltistan, HPO,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

WAPDA updated the Feasibility Study of the Project with enhanced capacity of 54 MW and therefore, detailed ESIA was required.

The following earlier project reports have been reviewed to assess their applicability in the prevailing environmental conditions specially in GILGIT-BALTISTAN Region:

- Bunji Hydropower Project: Feasibility Study Report (Vol-III), Environmental Impact Assessment by Bunji Hydropower Consultants (March, 2005).
- Detailed Engineering Design Report of Phander Hydropower Project.
- Feasibility Study Report of Shyok Dam Project, Environmental Impact Assessment Study.
- And Various Other Reports Related to Gilgit-Baltistan.

16.5.2 Acquisition of Secondary Data

The secondary data have been collected from various offices and published reports of different organizations in the Gilgit-Baltistan. These organizations included W & P Dept., Education, Forest, Agriculture, Fisheries, Sanitation, Wildlife, Environmental Protection Agency, District Administration, Tehsil Offices, Local Councils and others. The studies are carried out on the information received during field visits of Project Area, data received from some NGOs, water samples collected from Project Area at various places and tested in Environmental Protection Agency Laboratory, Gilgit, climate data received from Metrological Department, and other data taken from earlier conducted Feasibility Study and other reports of projects.

16.5.3 Collection of Primary Data

The primary data have been collected and assessed with reference to different project components, i.e. dam site, reservoir area, powerhouse, construction camps etc. The data regarding climate, hydrology, geology, seismology, neo-tectonics and other physical features of the Project Area has also been obtained as part of the preparation of this Feasibility Study

I. Vegetation and Wildlife Fauna Studies

The assessment area for terrestrial flora and fauna encompasses the terrestrial environments upstream and downstream of the dam and adjacent areas that may be affected by the project activities, specifically from the dam to the upper end of the reservoir impoundment and from the dam to the powerhouse.

Since the lake was formed in January 2010 and no new area would be submerged with the Project except the powerhouse site, therefore, there would be no new threat to plants with the construction of hydropower project. However, concentration has been given to study the rare species and special emphasis has given to the economic species such as medicinal plants.

Information on wildlife fauna species (mammals, amphibians, reptiles, birds etc.) in the assessment area has compiled based on opportunistic observation, gathering the existing information and consultation with local experts, community members and government and non-government organizations.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

II. Aquatic Ecology and Environmental Flow Study

Generally Northern Area is blessed with great water resources comprised of rivers, streams, and alpine lakes fed by the snowmelt and glacier waters. These freshwater resources harbor several fish species, which are the important component of the biological diversity. The fish fauna in Hunza Valley is relatively poor due to high turbidity, low water temperature and high water speed.

An environmental flow study has been carried out to determine the optimum environmental flow downstream of the proposed dam for sustainability of the aquatic ecosystem.

III. Social Surveys

The purpose of social survey is to record the present conditions of the people living in the Project Area and to assess the expected Project impacts on their life, subsistence systems, and social and cultural conditions. Prior to conducting the field surveys, the following steps have been taken:

- Geographic boundaries of the Project Area has been identified and listed existing villages and settlements.
- Decided the sampling procedure in order to draw a representative sample size of the target population and households.
- Developed the tools for data collection i.e. questionnaires for household sample survey, village profile, women sample survey, community participation and water use.

In order to obtain comprehensive and detailed information, the following techniques and tools of data collection has been used.

IV. Sampling Design

A stratified proportionate random sampling technique has been applied to select adequate and representative samples to generalize survey findings at the Project level. The stratification variables have been taken into consideration for enhancing the representation level for adopting appropriate sampling design.

V. Stratification Variables

The major objective of the study has to establish baseline socio-economic conditions for the inhabitants near the existing reservoir upto original extent of lake formed in 2010, powerhouse and adjacent areas of the Project. The following factors have been taken into consideration for enhancing the probability of every household being selected in the sample size:

Each village has been included in the sampling frame because of the heterogeneity of socio-economic characteristics between villages and relatively homogeneity within a village.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

VI. Sampling Unit

The primary sampling unit for the socio-economic survey is the head (male or female) of the household falling within the nine sample villages of proposed ALHPP Area.

VII. Basic Unit of Study

The basic unit of study and analysis for the purpose of socio-economic investigation is nine villages of Project Area for ALHPP.

VIII. Questionnaires

In order to test the validity and reliability of the proposed questionnaires, interviewing guides have been pre-tested in the area and then the questionnaires have reviewed to assess whether questions needed to be clarified, changed or re-sequenced and then a final editing of questionnaires has been conducted prior to their subsequent application in the real sample areas.

List of Respondents of socio-economic survey is attached at **Appendix-A** of **Volume-6** of Feasibility Study. The different questionnaires used for the social survey are included in **Appendix-B** of **Volume-6** of Feasibility Report.

IX. Field Investigators

A team of experts of Hydro Planning Organization (HPO) moved to Project Area for field investigations. The team hired services of one local graduate female and one local graduate man for questioning and answering with local people in their language. Additionally, the services of a local well educated female hired for the interviews and data collection covers the subjects of gender and women empowerment. The team spent more than three weeks to visit seven villages of upstream and two villages of downstream side of the Project Area. In this exercise both genders have been covered in field visits of Project Area. The field investigators (team) with interviewing skills minimize the sampling error and wrongly asked or interpreted or recorded answers to finalize a report with the respondents.

X. Interviewing Guide for Community Participation

Well informed persons in the village has been interviewed by using a questionnaire to obtain information about village and their perceptions about the Project.

XI. Household Sample Survey

Household heads of total sample size from each sample village of the Project Area have been interviewed by using structured questionnaires. Detailed information about the socio-economic status of the family and household has been obtained from the respondents.

XII. Village Profile

A comprehensive village profile has been prepared to document the socio-economic and demographic data of each sample village in Project Area.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

XIII. Gender Survey

The experts developed a separate questionnaire covering various aspects and issues of women in the area. The services of a qualified local female hired for this survey. Women from all the villages have been interviewed. Respondent women have been selected by applying the technique used for socioeconomic survey.

XIV. Data Editing

The filled-in questionnaires and interviewing guides have been edited by the same field investigators, who are involved in the data collection. This has been done immediately after completing the field investigations.

XV. Data Analysis

Data sets have been processed after the completion of the field survey and editing of socio-economic information. Analysis of this diversified data and preparation of conclusions in the minimum possible time has achieved using statistical techniques of data analysis.

All questionnaires sample are included in **Appendix-B** of **Volume-6** of Feasibility Report.

16.6 BASELINE CONDITIONS

This section provides baseline data (physical, biological and socio-economic parameters) related to the Project Area. Information provided is both quantitative and qualitative and is based on secondary and primary data collected, site field visits and desk studies. A baseline consists of the existing environmental and socio-economic and cultural status of the Project Area. The baseline information and indigenous knowledge is required for scoping potential environmental issues associated with the implementation of the Project. On the basis of baseline information, the Project interventions are assessed and mitigation measures are proposed. The baseline information also helps to indicate the specific issues to be monitored during Project execution as well as during operational phase.

16.7 PHYSICAL ENVIRONMENT

16.7.1 Physiography.

The site of the Project is located on Hunza River at Attabad Lake about 15 km upstream from Ganish Bridge of Hunza. Its distance is about 20 km from Hunza and 115 km from Gilgit. The powerhouse location is on the left bank of river and easily accessible from KKH. The intake weir/dam site is selected at current exit point of Attabad Lake which was formed in the year 2010 due to a huge slide from right bank mountain, however, some left bank mountain portion was also damaged.

16.7.2 Demography

Hunza Valley is mainly divided in three parts with different tribal structure. The people living in Gojal had migrated to this part of Hunza from Wakhan, Pamir and Badakhshan before the end of 18th century. They are mostly Wakhis (from Wakhan, a strip of land between Central Asia and Pakistan), an ethic group staying in the mountainous areas of the Karakoram and the

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Pamirs in the border land of Pakistan, China and Afghanistan. The language and culture distinguish them from Brush and Shina speaking people, who live in central and lower Hunza.

16.7.3 Climate

The climatic parameters that influence the climate of an area include temperature, precipitation, humidity and evaporation. Situated in the western most arm of Karakoram Range, Hunza is found within semi-arid and rugged mountain landscape (mountain desert). The climate varies widely from monsoon-influenced moist temperate to arid and semi-arid cold deserts in the North. In general, two seasons prevail in the Project Area: winter (October to March) and summer (April to September).

16.7.4 Precipitation

Rarefied air, intense solar radiation, strong winds, and vast ranges of temperature are the characteristic climate of the Area. Below 3000 m a s l, precipitation is less than 200 mm per annum while there is a sharp precipitation gradient along the altitude, and over 2,000 mm annual snow fall above 6000 m.a.s.l. Average Monthly and annual rainfall recorded at WAPDA High Altitude Weather Station has been given in Table 16-1

The Hunza River catchment upstream of the dam site is highly mountainous generally with low precipitation. The low precipitation particularly during the hot (monsoon) season coupled with less catchment area likely to experience rainfall are the factors responsible for low runoff or poor contribution to flood producing mechanism source. Hunza like other areas in extreme North-West of Pakistan receives only 136 mm precipitation of which 40% occurs in Winter and Spring.

16.7.5 Temperature

Temperatures in the valley bottoms can vary from extremes of 35°C in summer to less than –15°C in winter. The summer season in Hunza Valley is cool while winter is chilly. Wide spread snow fall occurs in winter. During winter the northern winds blow constantly bringing the temperature down considerably. At Hunza, the mean maximum temperature is 23.8□C in July, the hottest month and the coldest month is January with an mean minimum average temperature of -1.9□C. The Gilgit Meteorological Station is the nearest station to Hunza Valley that has a sound historical record covering more than five decades

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 16-1 Average Max & Min Monthly Temperature and Mean Precipitation at Gilgit

Month	Mean Min Temp (^{O}C)	Mean Max Temp (^{O}C)	Mean Prec. (mm)
Jan	2.4	9.4	4
Feb	0.7	12.6	6.8
Mar	5.7	18.2	0.14
Apr	9.5	24.1	23.8
May	12.1	28.6	24.5
Jun	15.1	34	8.8
Jul	18.4	36.1	14.6
Aug	17.8	35.3	14.6
Sep	12.7	31.7	7.6
Oct	6.8	25.5	6.9
Nov	0.9	18.2	2.4
Dec	-1.9	11.5	5.1
Annual Mean	**7.9**	**23.8**	**133.1**

16.7.6 Geology

Tectonically, Project Area lies in the Karakoram Block towards the North of the Main Karakoram Thrust (MKT) and Main Mantle Thrust (MMT) which are considered to be the manifestation of the tectonic collision between Indian Plate (Continent) with the Kohistan Island Arc and then with the Eurasian Plate (Continent). This continent to continent collision has given rise to three most famous orogenies in the world. The Himalaya, Karakorum and Hindukush are considered to be the highest mountainous ranges in the world.

The Glacio fluvial deposits forming the site of Attabad Village consist of boulders, cobbles and gravels with some silt and sand as cementing material. The rocks exposed at the crown and toe; are highly fractured, sheared, jointed and weathered. A fault on the eastern side of the village is passing through Hunza River trending almost North-South. The re- sediment till deposits flank both sides of Hunza River in the powerhouse area. These tills comprise extremely fine grained (powder) soapy-touch clays.

16.7.7 Seismology

The Project Area lies in the Northern Region of Pakistan which has high frequency of earthquakes especially in the Himalayan orogenic belt. This belt represents the contact between Indo-Pak and Eurasian plates, which has always been the source of moderate to large earthquakes including Kangra (1905), Bihar-Nepal (1934), Assam (1897) and 2005 Kashmir earthquakes with significance consequences.

In October 2005, an earthquake of very high intensity (7.8) hit the area near Muzaffarabad and disturbed the ground to a significant extent in that area. The geological, tectonic and geodynamic conditions of the Project Area have been assessed and detailed mapping of the ground surface has been done to define the geology and tectonic features of the Area.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.7.8 Landslides, Erosion and Sedimentation

Landslides are very common features in the Project Area because of the high steep terrain. Erosion and sediment input to the river is a function of landslides and riparian erosion processes. There are frequent talus accumulations along the side slopes of the river. These are typically in a state of stable equilibrium at their current slope angle and environment but become unstable when the equilibrium is disturbed. Excess water and earthquakes often trigger landslides.

16.7.9 Land Use

There are nine villages located on alluvial fans and terraces on both sides of the Hunza River and its tributaries where water is available for human consumption and agriculture. The nallahs span out near the confluence of the river, forming some cultivable land masses as can be witnessed near Passu Village. The available flat land is used for residential purposes as well as for agriculture, orchards and grazing for cattle, goats and sheep etc. The total geographic area of the Hunza Valley is about 8,920 km2. Summary of land use in the Gilgit-Baltistan is shown in Table 16-2

Table 16-2 Summary of Land Use in Gilgit-Baltistan

S.No.	Type of land	Area Million (Hectares)	Percentage (%)
1	Mountain/Lakes/Rivers/Glaciers	4.810	66.3
2	Protective Forests	0.065	0.89
3	Private Forests	0.219	1.78
4	Social/Agricuture Forests	0.368	5.07
5	Range lands	1.626	22.4
6	Cultivable Area	0.078	1.1
7	Cultivable Waste	0.090	1.2
Total		7.250	100%

Source: Statistical Unit GILGIT-BALTISTANP & DD 2013

16.7.10 Mining

Mining is one of the common professions in small parts of the Project Area. The area near the lake is rich in mineral resources however their exploitation as commercial use is still not being done. People use to explore the mines by their own resources without any support of Government.

16.7.11 Agriculture

The area under agriculture is approximately 112,688 ha or 1.6% of the total area Gilgit-Baltistan. Because the climate is arid, agriculture depends on irrigation through water channels locally known as (kuhls) - that bring water through gravity flow from streams fed by glacier or snow melt. Agricultural in Gilgit-Baltistan can be divided into two broad cropping zones depending on the elevation. At elevations between 1200 and 2000 m a s l both summer and winter crops are grown, however, in areas situated in between 2000 and 3000 m a s l a single summer crop can be grown.

In Hunza District, the general combination of crops, livestock and other farm related activities are more or less the same. Wheat, barley and vegetables are the main Rabi crops. Whereas

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Maize, potato, millet and pulses are Kharif crops. Shaft all and Lucerne or Alfalfa is grown as a perennial crop which is the most popular fodder for livestock throughout the year. District wise Agriculture Land of Gilgit-Baltistan is shown in table 16-3.

Table 16-3 District Wise Agriculture Land of Gilgit-Baltistan

District	Agriculture Land (ha)	Percentage Cover
Astore	8133.43	1.51%
Diamer	9058.52	1.26%
Ghanche	11966.75	1.35%
Ghizer	16431.94	1.34%
Gilgit	10167.94	2.44%
Hunza-Nagar	12013.87	0.8%
Skardu	30589.88	1.56%
Total	**98362.33**	**10.26%**

16.7.12 Fruits

Gilgit-Baltistan is producing many fruits like apple, cheery, walnut, and apricot. But apricot is more famous for its test and quality. Pakistan produces approximately 300,000 tons of fresh apricot, making it the world's fourth largest producer. Gilgit-Baltistan and Baluchistan are the two main apricot growing regions in Pakistan, with Gilgit-Baltistan alone producing 114,286 tons in 2007. Planting density is only 230 trees/ha, which is much less than the recommended 750 trees/ha, due to apricots being planted around field edges, rather than orchards. Average yields of fresh fruit are 38 kg/ tree which are good considering the limited use of inputs, although yields of 50 kg/tree can be achieved through improved management.

At higher altitudes there are no fruit trees, but in lower portion of Hunza Valley several types of fruit are grown. Major fruits are apricot, apple, mulberry, grapes, almond and walnut. It has been calculated on average that every household has 22 trees out of which 15 are fruit bearing trees. The average production of fruit by each tree is 50 kg.

16.7.13 Livestock

The people of entire Hunza River the livestock reared by almost all households. Usually with the snow melt, goat, sheep and cows giving no milk are taken to the Alpine Pastures for grazing. They stay there during the summer season and are brought back with the onset of snow on the top of the hills. When the animals are brought to the village they are grazed in the agricultural fields of maize crop residues. All the milking animals are kept in the houses and stall fed.

Livestock contributes a great deal to the local economy. However, physical condition and general health of the animals is not satisfactory, especially in winter due to the shortage of fodder. Bullocks are the main source of farm power, but they are hardly capable of drawing plough due to poor health. Cows, sheep and goats are also lean and thin. Animal diseases cause considerable losses to the livestock. Productivity of cattle is generally low because of severe winter and lack of proper feed. Meat, milk, butter and eggs are the main animal /poultry products but most of these are consumed at the household level. At some places milk, meat, animal hides, wool and poultry are sold.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.7.14 Hydrology

The main tributaries of Hunza River are; Chapursan, Kilik, Bola Das joining the Hunza River from the west and Khunjerab along with Ghujerab, Simshal and Hispar Rivers joining river from the east of the valley. The river flows of Hunza are usually maximum in the month of July when snow and glacier melt is at its peak while these are minimum in the month of March when snow and ice melting is insignificant.

There is only one hydrological gauging station on Hunza River at Danyor Bridge being operated by SWHP-WAPDA. This station is located at about 107 km downstream of Attabad Landslide Dam. The catchment area of Hunza River upto Danyor gauging station is 13,157 km2, whereas it is 14,083 km2 upto its confluence with Gilgit River. Hunza River catchment area is 8,901 km2 upto Attabad Landslide Dam. Therefore, river flows are transposed and estimated from documented discharge data from hydrological station at Danyor. Daily discharge data from 1966 to 2015 is available and processed for the calculations. Data for year 2016 was incomplete, missing the values of high flow months, and there was no record of hydrological data for the period 2017 to 2018 at SWHP therefore, it was not used in the calculations. Mean annual flows are calculated and drawn in the figure below for the period 1966-2015. Average value for mean annual flow has been calculated as 208.36 m^3/s.

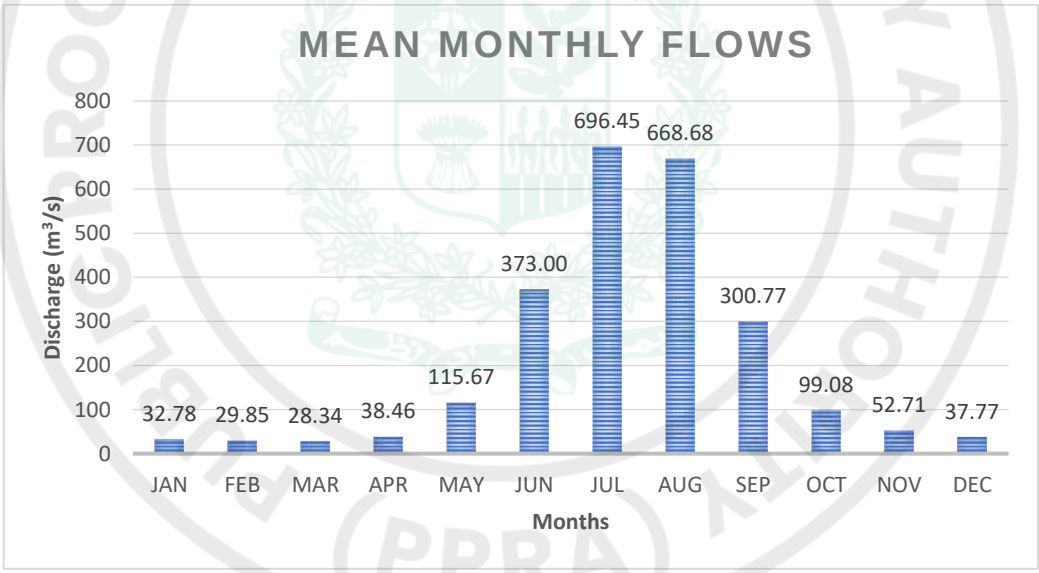

Figure 16-2 Mean Monthly Flows

Flows are generally maximum in July and August almost reaching 700 m^3/s. Whereas, flows are low from December to April each year when snow falls in the catchment. The record shows that design discharge of 60 m^3/s is available for about half year (almost 6 months). Graph shows that flows are exceeding the design discharge from June to mid-December which shows the potential of hydropower generation.

The maximum peak discharges of mean daily for every year recorded. The instantaneous peaks will definitely be higher than the measured daily flows and can be enhanced while execution accordingly. Instantaneous peak flows for the period 1966 to 2015 has been calculated and plotted as well.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

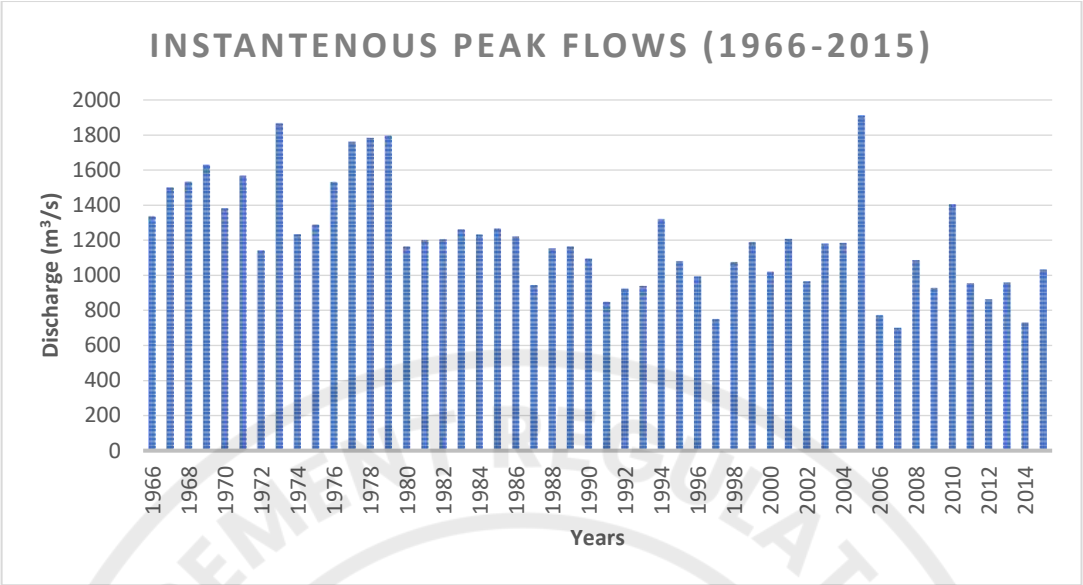

Figure 16-3 Instantaneous Peak Flows at ALHPP

16.7.15 Surface Water Availability & Quality

In the Project Area, the Hunza River carries water of various streams (nallahs)of snowmelt, and rainwater fall. The people use the water of these nallahs for drinking, household and agriculture purposes. Generally, there is no shortage of clean potable water in the Project Area as it is very difficult to fetch the water of river and nallahs due to the very steep slopes. People mostly use water from nallahs for drinking, washing and other domestic purposes. During the socio-cultural survey of the Project Area, many of the respondents from the villages reported stomach, skin, bones, diseases. Initially, rainwater as well as snowmelt water do not contain significant impurities. As these waters flow over land they pick up sediments, salts, toxic elements, pulverized organic matter and bacteria from the surface. Water samples were taken in November, 2020 covering the complete affected area within the project area. The laboratory results of these samples summarized in Tables given in volume 6and detail at Appendix-C reveal that all the parameters are within the permissible limits when compared with drinking water quality standards of WHO, except the presence of Escherichia Coli Pathogenic Bacteria which causes gastroenteritis in human beings.

Piped water supply that covers only 40% of the total population of the Gilgit-Baltistan does not provide safe/ clean drinking water to urban and rural settlements in the Region. In upper Hunza Region, drinking water is obtained from glacier melt and piped water only in summer season.

16.7.16 Groundwater

The Project Area consists of rocky mountainous terrain. The water originated from rainfall and snowmelt flows through streams and enters into river. Only a small quantity of water has the chance to percolate and form a groundwater reservoir.

16.7.17 Air Quality and Noise

The air quality of the Project Area and its vicinity is very fresh and clear under normal condition. Air and noise pollution has not yet emerged as an environmental issue owing to operation of a

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

small number of vehicles increasing by a fair degree during the tourist season. Based on a number of observations on ambient air quality in rural areas the following range of concentration of gaseous pollutants is estimated on the roadside at Gulmit

Table 16-4 Range of Gaseous Pollutant Concentration & Noise Emission Level

Range of Variation	CO ppm	SO_2 ppb	NO_x ppb	SPM $\mu g/m^3$	Noise dB(A)
Minimum	0.65	05	05	45	40
Maximum	0.9	10	12	90	70
Average	0.7	07	07	70	55

The noise level near the river is fairly high and range between 50 to 65 dB without traffic, mainly due to the flowing water colliding against rocks and boulders. There is normal traffic on the KKH which runs through the Hunza Valley. So traffic noise has negligible contribution to the noise level in the Project Area.

16.7.18 Greenhouse gases

Greenhouse gases are those gases (CO2, CH4, O2, CFCs and NO) which contribute to global warming. The main sources of these gases are industries and vehicles using fossil fuel as fuel. At present there is no industry in the Project Area that emits greenhouse gasses (GHG) and vehicles intensity is also very low. The main sources of carbon and nitrogen oxide emissions are due to automobiles in the Project Area.

16.7.19 Waste

The villages within the Project Area do not have any drainage, sewerage or treatment system for sewerage collection and disposal. More than 50 percent of the houses have improvised pour flush pit latrines. The remaining 50 percent of the house hold use locally made toilets. Waste water(sludge) from kitchen, bathing and washing is discharged into small drains/water courses leading to the nallah or directly to small fields outside the houses. Animal waste especially cow dung is used for farm manure or used for burning after drying (though rarely).

16.8 BIOLOGICAL ENVIRONMENT

Habitat loss is considered as the leading cause of loss of world's biodiversity. Most species need undisturbed habitat to find food, water, shelter, and mates. But people are altering habitats all over the world. In such areas, the activities causing habitat loss include commercial logging (not based on technical and sustainable basis), land development, over-grazing, fuel wood collection, construction of roads, and building new settlements. All these actions change landscapes, natural water flows, and the species composition in the area. Moreover, changes in climate and land use patterns also reducing the amount of snowfall and rain upon which the habitat depends.

16.8.1 Flora

A study was carried out on the Biodiversity of Khunjerab National Park (KNP) during May and June, 2006 to establish baseline information about existing plant wealth and wildlife including

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

flora, reptiles, bird, sand mammals in order to make some vantage points for future monitoring of key wildlife species. Using different direct and indirect investigation techniques, 14 different valleys and Nullahs of KNP were surveyed and observations on various habitats were recorded.

Four types of vegetation zones were identified including Dry Alpine Scrub, Moist Alpine Pastures, Dry Alpine Plateau Pastures and Sub Alpine Scrub and Birch Forests. So far, 62 plant species belonging to 45 genera and 25 families were identified. Of them, 4 grasses and one species of Liliaceae were determined. Details of flora zones and further types are described in the **Volume-6** of this report.

16.8.2 Forestry

Forestry is important for fuel, timber, in addition to control of the soil erosion and reduction silt load in lakes and rivers. In the Gilgit-Baltistan only Diamer district is rich in forest while the other five districts including Hunza have nominal forest of Juniper. The forests consist of blue pine, spruce, willows and shrub consist of rosa species.

16.8.3 Fauna

This diverse range of vegetation and ecological zones also supports a rich faunal diversity, including an estimated 54 species of mammals and 230 species of birds. About 23 species of reptiles and 6 of amphibians have been reported from Gilgit-Baltistan. Among reptiles 9 species are of lizards and 14 of snakes, while among amphibians 2 species of frogs and 4 of toads. Very little information is available on insect diversity in Gilgit-Baltistan, however, about100 species of butterflies have been reported from Gilgit-Baltistan.

Several globally threatened species – including the snow leopard and Markhor – continue to survive in Gilgit-Baltistan in significant numbers. The flora and fauna belong to Palearctic region. Fifty-four species of mammals have been reported in Gilgit-Baltistan, which comprise 1 shrew, 10 bats, 18 carnivores, 6 artiodactyls, 3 lagomorphs, and 16 rodents. The region is also home to a few globally threatened species like Snow Leopard, Himalayan lynx, Marco polo sheep, Blue sheep, Ladakhurial, Markhor, Musk deer, and Woolly Flying Squirrel. The resident avifauna includes Monal pheasant, Snow Partridge, Himalayan Snow Cock, and several birds of prey species.

Occurrence of some rare species has been reported in Gilgit-Baltistan. These include species like Lammergeyer and Golden eagle. Few sightings of Lesser Kestrel have also been reported in lower Hunza near Hunza river. The main diverse group of birds in NA is the Passeriformes species. These are mostly Warblers, Tits, Flycatchers, and Buntings. Some of the restricted range species like Snow Partridge and Himalayan Monal pheasant are extremely rare and may be at the verge of extinction from many of their earlier strongholds. According to Birdlife International (2001) report there are 27 species of Pakistan, which are threatened internationally out of which 7 species are found in Gilgit-Baltistan.

Hunza is very scattered settlement with meager population. Considering its wildlife resources to be protected and preserved. Shooting, trapping of wild animals is not allowed except with a special permit. The number of animals or birds killed or captured is also restricted and specified in the permit. Snow leopard and Ibex are already declared as endangered and other species of mammal are also scarce. But trophy hunting is allowed which is beneficial to the local

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

community as the 70% of the funds go to local community which is used for the development of the local area.

Table 16-5 Fauna available in Gilgit-Baltistan

English Name	Urdu Name	Scientific Name
Ibex	Kill or Kil	Capra ibex sibirica
Snow Leopard	Cheeta	Pantherauncia
Red fox	Lombrei	Vulpesvulpes

Eagle	Shaheen	Aquila Chrysaetos
Hawk	Gid	-
Falcon	OoqaaborOoqabaa	-
Pie	Jample	UrocissaEryphrohyncha
Hopoe	Hodhodh	Upepaepaps
Pigeon	Kabutar	-

16.8.4 Insects

The Project Areas is rich in biodiversity of insects including butterflies found in the Project Area, particularly during the humid months of July and August. In addition, caterpillars, bugs, beetles, black bees, weevils, mosquitoes, ants, green aphids, codling moths, leaf miners, mitts, fruit flies, woody aphids, stray grass hoppers, leaf hoppers, mealy and woolly bugs, peach leaf curling aphids, scale insects, walnut weevils, blister mites, and dusky veined aphides are all found in the Northern Areas including the Project sites.

16.8.5 Protected Area

In order to safeguard the biodiversity of key ecological systems, Government of Gilgit-Baltistan has declared four National Parks to protect and conserve bio-diversity of Gilgit-Baltistan. These include Handarb National Park, KNP, Deosai National Park and Central Karakorum National Park. In the protected forest, the forest owned by Government as per Forest Act-1927, all activities are prohibited until and unless permitted by the government. Usually, removal of fallen, dying, and dead trees is not banned, however, grazing, sometimes, is regulated to ensure regeneration. In GILGIT-BALTISTAN, designated protected forests cover an area of 445,712 ha and are mostly found in Ghizer, Astore, Skardu and Gilgit Districts. Out of that 64,512 ha is conifer forests while 3, 81,200 ha are scrub forests (IUCN, 2003).

Aga Khan Rural Support Programme (AKRSP), International Union for Conservation of Nature (IUCN), Wildlife Conservation Society (WCS) and World Wide Fund (WWF) are the main international organizations who over the last two decades have played a crucial role in creating awareness among communities for sustainable management of biodiversity resources. The

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

then Ministry of Environment also implemented a Program for Mountain Areas Conservation (PMAC) to promote biodiversity conservation in Gilgit-Baltistan through community participation. This program was completed in 2011. As a result of these efforts the GILGIT-BALTISTAN offers a model for community based management of forestry resources.

Despite of all these conservation initiatives and efforts by government and international organization, fast depletion of forest ecosystems has been observed in the last two decades. The following strategies and actions will be taken to achieve the objectives of conservation, sustainable use and equitable sharing of benefits.

16.8.6 Aquatic Ecology

GILGIT-BALTISTAN is blessed with highest potential of cold and clean water resources in shape of lakes, canal, reservoirs, rivers, and water logged areas that offer ideal habitat for trout and other cold water fish species. There is dire need to get maximum benefit from these resources through technological advancement in production, processing and marketing. Both the public and private sector are fully involved in order to judicially exploit this potential both in natural waters as well as its development in culture conditions. The fish fauna in Hunza Valley is relatively poor due to high turbidity, low water temperature and high water speed.

16.8.7 Fisheries

Fisheries department Hunza was established in the year 2012 with the core aim to develop and promote Fisheries and aquaculture activities in newly created district. District Hunza has very rich aquatic resources of aquaculture and fisheries in forms of bluish lakes, gashing rivers, torrential streams, seasonal and perennial springs etc. Fisheries department Hunza has come up with novel approach and ideas to get maximum benefit from wise use and sustainable exploitation of natural resources in multiple ways with special focus on introduction and installation of cage culture system in Attabad Lake under controlled environment to enhance production with stocking and multiplication of fine verities of fish in nature. At the same time, it has also been planned to promote sport fishery providing enabling environment and other related facilities for tourists and fish anglers.

For this the Attabad Lake having crystal clear water offers as natural gene pool reserve, ideal for excessive multiplication and better growth of many indigenous and exotic fish species

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 16-6 Potential Fisheries Resources in District Hunza

I. Salmo TruttaFario (Brown Trout)

II. Onchorynchus Mykiss (Rainbow Trout)

16.8.7.2 INDEGENOUS FISH SPECIES

Among the 15 identified indigenous fish species in Gilgit-Baltistan the following six fish species found in District Hunza:

I. Shizothoraxplagiostomus

II. ShizothoraxNasus

III. PtychobarbusConirostris

IV. TriplophysaTerwasae

V. TriplophysaYasinensis

VI. DiptychusMaculatus

16.9 SOCIAL AND ECONOMIC ENVIRONMENT

16.9.1 Population

The population in Gojal consists of 51% male and 49 % female; it has a population density of 17 persons/acre. The child-women ratio of the study area is 345 children per 1000 women. The dependency ratio is 142 % in Hunza Valley, which shows that there are about 3 dependents on every two earning members. The average size of household is 7.26 persons. The average size of family is 7 persons per household, while the density of room is 4 rooms per household.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

In the study area of Gulmit, Shishkat and Passu total number of households according to the census 2017 is 8697 people, these are the areas surrounding the Attabad Village. The detail of population is shown in table

Table 16-7 Population of the Area (2017)

Name of Jamatkhana	No. of household registered	Actual Population
Gulmit central	142	963
Kamaris	42	319

Total	**1108**	**8697**

Source: Gulmit Local Council

16.9.2 Languages

Burushasky and Wakhi are the main languages of Hunza Valley. There are some other languages in the region are

- Shina.
- Burushasky.
- Khowar.
- Balti.
- Domaaki.
- Wakhi.
- Gojri.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.9.3 Ethnic Groups and Religions

Almost, 95% of the people living in Hunza Valley and 100% in Upper Hunza belong to Ismaili faction with his highness Prince Karim Aga Khan as their spiritual leader. 5% in Hunza Valley are members of Shia Imami faction which is concentrated in the village Ganish and surrounding settlements.

16.9.4 Administrative Setup

Hunza remained an independent state after 1947 while still staying under the control of the Islamic Republic of Pakistan. The last Mir (Jamal Khan) and his family were retired and the Mirdom was abolished, and Hunza became a subdivision of the Northern Area in 1974. The government tried to establish administrative structure in the valley. The abolition of the traditional institutions left a gap that was partly filled by institutions established under projects of the Aga Khan Development Net Work (AKDN), which started operation in 1979.

16.9.5 Health Facilities and Common Diseases

The villages in the Hunza Valley have somewhat better healthcare facilities than rest of the Gilgit-Baltistan except Gilgit and Skardu. Aga Khan Health Service (AKHS) and Government health workers are providing health facilities in the area. They provide first aid facilities and also give family planning guidance to the people. Gulmit Government hospital was established in 1980.

16.9.6 Education and Literacy

Almost all the settlements in Hunza Valley have a high literacy rate. There was no school before 1946 in the villages of Gojal. Diamond Jubilee School for Boys was established in the Gulmit on the occasion of the Diamond Jubilee Ceremony of Sir Sultan Mohammad Shah, Aga Khan III in 1946. At present there is one Government High School for Boys and one D. J. High School for Girls, besides one public high school: Al-Amin Model School for boys and girls. There are two primary schools in Hussaini village. Literacy rate in Hunza is almost 95% which is higher than other districts of Gilgit-Baltistan. Girls in Hunza are enthusiastic about their future so they prefer to have higher education. For higher education students go to KIU Hunza Campus in central Hunza; a number of boys and girls are studying in Gilgit, Islamabad, Peshawar, Lahore, and Karachi for higher studies.

16.9.7 Infrastructure and Recreation

Infrastructure facilities including health, education and transportation are available in Hunza Valley to those near the KKH. Construction of Karakoram Highway (KKH), the Silk route or Pak China Friendship Highway, was started in 1965 and was completed in 1986. The KKH starts from Thakotin KPK and continues up to Khunjerab Pass; it has over one hundred bridges. The length of KKH is 1300 km and width is two lanes. KKH has played an important role in the development of Hunza Valley. Buses and vans are used for traveling in Gojal from and to Gilgit and down areas of the country. Public transport is provided by both Private vans and Government buses (NATCO). The impact of the KKH is very conspicuous on the socio-economic condition of the villages. KKH provides an important link between Pakistan and China. This road serves the tourist traffic and acts as supply route for the mountaineers to the down country and other neighboring countries.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Recreation and tourism has grown in the area rapidly, which in future can become an important source of income.

16.9.8 Professions and Source of Income

The people of the area are linked with different professions like tourism sector, business, livestock, dry fruits, trade and government jobs.

16.9.9 Tourism and Cultural Heritage

Hunza is the tourism and business hub of Gilgit-Baltistan thus a large number of residents from this area directly or indirectly involves either in business or work in tourism sector

16.10 ESIA AND MITIGATION MEASURES

Determining the significance of impacts identified is one of the main purposes of an ESIA and it enables the identification of necessary mitigation and a determination of environmental and social costs associated with the Project. Environmental and social impacts of any Project are identified taking into account all phases of the project cycle, including planning, construction, operation and decommissioning. The environmental issues and impacts of a project depend upon the nature of the project activities, and the types and extent of interventions involved. It is not easy to predict the future and assign a relative value or overall significance to an impact, since every impact has a different and multi-dimensional nature, and also because it involves personal and subjective judgment for many attributes. An environmental or social impact can be either beneficial or adverse and is assessed by comparing the quality of the existing environment with the predicted quality of the environment once the project is in place. This ESIA identifies the impacts likely to arise as a result of construction and operational activities and assesses the likely magnitude of the impact in order to provide some indication as to which impacts are likely to be most significant. The impact assessment has been based on that environmental checklist developed by the Asian Development Bank (ADB).

16.11 IMPACT ASSESSMENT PROCEDURE

In order to describe the significance of an impact it is important to distinguish between two concepts: sensitivity and magnitude. As far as possible the sensitivity and magnitude of the impact are described with reference to legal requirements, accepted scientific standards or accepted impact assessment practice, and/or social acceptability. Where no known published ‘standard’ criteria exist for determining the magnitude of effects, established professional criteria and best practice techniques are used and clearly described.

16.11.1 Sensitivity

Sensitivity is generally sites pacific and criteria are developed from baseline conditions. The sensitivity of are captor is determined based on review of the population (proximity/ numbers/vulnerability), presence of biological features of the site or the surrounding area, soil, agricultural suitability, geology and geomorphology, existing air quality, presence of any architectural and historic heritage, landscape etc. Sensitivity, relates to the value, importance and tolerance of an environmental resource or receptor and should take into account where possible stake holders views and public acceptability. Sensitivity can be categorized as high, medium, low, and negligible to the assessment of receptor sensitivity.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.11.2 Magnitude

The assessment of magnitude is undertaken in two steps. Firstly, the key issues associated with the Project are categorized as being either adverse or beneficial. Secondly, beneficial and adverse impacts are then further sub divided into major, moderate, minor or negligible based on consideration of the parameters listed below:

- Duration of the impact
- Spatial extent of the impact
- Reversibility
- Likelihood; and
- Legal standards and established professional criteria.

In order to make the report as meaningful and useful as possible, an attempt has been made to describe each impact in the following terms: positive impacts refer to beneficial effects and negative impacts refer to harmful effects on e.g. natural resources, human beings and economy

16.12 IMPACTS DURING CONSTRUCTION AND OPERATIONAL STAGE

During the construction phase of the project most of the impacts identified are of a negative nature but some of them will be temporary and will vanish with the completion of Project.

16.12.1 Impacts on Topography

The interventions of the ALHPP are not likely to impact the topography of the area on a large scale except for those areas where the physical activities of excavation, digging and movement of the heavy machinery will take place Similarly, areas where excavated material from tunnels will be disposed, dumped or stored will be negatively affected. This impact can be considered as a negative impact with moderate magnitude during construction while there will be no impact on topography during operational stage.

Mitigation

To reduce the negative impacts of excavated material: firstly, the emphasis should be to reduce the volume of material requiring disposal and secondly, to dispose it in environmental friendly way. The following measures are proposed in this respect:

- As far as disposal on the dam site area is concerned, some of the spoil can be used for construction project related structures.
- Some of the spoil can be used for widening of the roads. Part of the excavated material on the powerhouse site can be used for making aggregate required for project construction and for the development of infrastructure such as roads and filling of natural depressions.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.12.2 Impact on Seismicity

The area is well known to consist of active landslide zones as more than 33 damaging events have occurred in the region during the period from the year 1830 till January 2010 (Kreutzmann,1994). In addition to this, according to the Geological Survey of Pakistan (GSP) a fault line also passes through the area. During the devastating 2002 earthquake in Astore that hit Attabad, the process of crack evolution in the mountains of Attabad Region was observed, which worsened during the subsequent strong earthquake (7.5 on Richter scale) in 2005. With the passage of time, cracks began to widen slowly and gradually on January 4, 2010, slope failure occurred in the Attabad Region resulting in the establishment of a natural dam that completely blocked the Hunza River. According to the initial estimates, a slide mass of approximately 30 million m^3 fell from the northern valley wall.

Mitigation

All structures to be built must be designed giving maximum allowance to seismic factors. A very careful analysis of the situation will be required during the design stage of the project by specialist consultants.

Continuous monitoring of the behavior of faults will be required during the operation stage and contingency plans to deal with such a situation must be part of the project management. Instruments to monitor seismic activity must be installed at the time of construction

16.12.3 Impact on Geology

Almost all project interventions involve excavation of natural rocks, cutting of formations, moving and dumping of spoil. During tunnel excavation and some other operations, blasting of the formation will be required. All these activities will disturb the existing geological formations and consequently physical features of the local geological formations of the project area will be damaged at some places, which is a negative impact of moderate magnitude.

During operation of the Project the seepage from the reservoir will significantly impact the geology of the area. The seepage water will saturate the formation below and along the reservoir and soluble minerals from the rocks will dissolve in the water. Some solution channels may develop in the formation making the formation more pervious.

Mitigation

All these activities are an integral part of the project interventions and cannot be avoided. Blasting should be minimized where possible (near the surface) and, if unavoidable low power explosive should be used and a greater number of blasts with low power material may be preferred instead of high intensity single blasting.

It is difficult to check or reduce the seepage from the reservoir. A continuous monitoring system will be required during operation of the project to monitor the changes in groundwater level and chemistry of ground water.

16.12.4 Impacts on Landslides

As the natural dam had been a result of a major landslide, therefore, special emphasis should be given to this aspect. Landslides are common in the project area due to the high steepness,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

unstable geological formations on both sides of the river and common seismic activities. Due to the Project activities, especially blasting of rocks in some areas, the formation will become loose and the risk of landslides will increase in the immediate vicinity of the construction sites specially at the right bank of Hunza River, which may be considered as a moderate negative impact of the Project.

Mitigation

To avoid the major risks, all structures are proposed on the left bank of Hunza River. Further, to minimize blasting of formations and, if unavoidable, then use low intensity explosive if possible.

It is expected that landslides could increase due to construction activities. Further the seepage of water will make the formation loose and unstable and the chances of sliding due to rainfall, abnormally high and low temperatures and due to seismic activities will increase. The sloughing and slippage of saturated formation during regular flushing of the reservoir may also enhance the sliding potential of the area. This impact may be considered as a major negative impact.

As no mitigation is possible to check either the seepage or any resulting landslide, however, as after a few years of Project operation most of the rocks along the weir site will become stable.

16.12.5 Impacts on Land Use

There will be no major impacts on the land use of the area as the lake has already been formed and changes has already been taken place long before this Project. However, new infrastructure will be built in the area which would have positive impacts on the land use.

16.12.6 Impacts on Infrastructure

As there would be no resettlement involved in the project, therefore, impacts on infrastructure would be rather positive.

16.12.7 Impact on Climate

Project construction involves large scale activities including the movement of different types of light and heavy traffic, working of heavy machinery, blasting of rocks, operation of batching and mixing plants and the presence of large numbers of people in the area. Due to all these activities, it is expected that the microclimate of the project area (surrounding the dam site and powerhouse site) will suffer significantly. However, no impact on climate of the whole project area is expected, either positive or negative, during the construction phase.

The lake has already been there since 2010, therefore no major changes would occur to the climate after Project has been completed.

Mitigation

The deterioration in the local climate during the construction phase will be of a temporary nature and will disappear with the completion of the project.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.12.8 Impacts on Hydrology

During the construction and operational, stage there will be no change in the hydrology of the river. The flow from the reservoir will be diverted to downstream of the weir through diversion channel.

Mitigation

To conserve the aquatic life (flora and fauna) of the river downstream of the weir (2 km patch), minimum flow of 3 m³/s has been calculated as the environmental flow. It will be obligatory for Project Operating Agency to release 3 m³/s in the river throughout the year as environmental flow.

16.12.9 Impacts on Sedimentation

During the construction stage, the overall sedimentation rate will remain almost the same upto the dam site, but it may change because of movement of heavy traffic, dumping of the excavated material and other Project related activities. The impact is considered as negative but of short duration and of minor magnitude.

The Hunza River water always contains huge sediments of around 20-21 Million Tons annually on average. Diversion Channel will be used for flushing of sediments during high flow months. It is expected that release of sediments in moderate quantity could change the morphology of the river d/s of dam. However, as sediments will be released during high flow months with relatively high velocity of water and the river in this section has a high gradient, it is expected that sediment will move far away from the downstream of the weir site.

Mitigation

The silt clearance (flushing) mechanism has been provided in the Project design through channel/sluices. It is proposed to flush the reservoir regularly during high flow months.

16.12.10 Impacts on Flooding

Flooding of the river at the dam site is not a common feature although some floods of high intensity are recorded in the past e.g. the glacial lake outburst floods of 1929. As river water from the upper cofferdam will be passed through diversion channels, there is chance that these tunnels could not accommodate the flows in any abnormal year. In such cases, floodwater can overtop or breach the cofferdam and damage the partially constructed civil works and lower cofferdam. Thehas significant positive impact.

Mitigation

The design of the weir has considered the design flood of 1 in10,000- year flood of 3,250 m³/s

16.12.11 Impacts on Groundwater

During construction stage, no impact on groundwater is envisaged as the flow of water will continue as such without any storage. The lake has already been formed, therefore, there will be no change to the groundwater.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.12.12 Impacts on Air Quality

The project activities during construction at both weir and powerhouse sites will involve large movements of heavy diesel operated machinery and vehicles which produce more noise and emit more smoke. Similarly, various levels of noise and air pollution are expected to be generated from construction machinery and equipment, working of heavy earth moving machinery, drilling, blasting operations, concrete mixing, pouring equipment and stone crushers etc. The impact on air quality is considered as short duration negative impact of moderate magnitude.

Mitigation

The contractors and sub-contractors must be held responsible through special clauses in the tender documents to strictly follow precautionary measures.

16.12.13 Impacts on Terrestrial Flora and Fauna

The Project Area has very thin vegetation cover due to the special features of the terrain i.e. poor rainfall and steep mountains with very little soil cover. During construction stage, the damages to flora can be done by vehicles and machinery, establishment of camps and permanent structures etc. The construction activities will generate impacts of negative nature on all types of fauna but of moderate magnitude.

Mitigation

Dumping of construction materials should be avoided where large number of terrestrial trees, shrubs, herbs, grasses and fruit trees are found. where mammals, amphibians, reptiles and birds settle.

There would be no significant impacts on Flora and Fauna of the micro environment of the Area during operation stage.

16.12.14 Impacts on Employment Opportunities

At present employment opportunities in the Project Area are limited to few fields which would increase with the construction and operational activities. Majority of local employees will be engaged in the unskilled and semi-skilled sectors. Employment generation is a major positive impact of the Project.

Enhancement

The contractors of the project components shall be bound legally through contract agreements to engage 100% unskilled labor from Project Area of Hunza Region. Preference should also be given to local skilled and semi-skilled manpower if available.

16.12.15 Impacts on Regional Safety and Health

People of Hunza used to interact with people from different areas, cultures and communities. However, when there is sudden influx and congestion of people at any place from other areas for a longer period of time, it may contribute to adverse effects on the community health, safety and security of locals. There is always potential for such social impacts as incidences of accidents, social conflicts, theft and spread of communicable diseases.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Mitigation

The contractors must be bound to establish workers camps sufficiently away from the settlements of local people. During construction, the Project working sites need to be bordered by a fence to safeguard life and property. As appropriate, any warning signs related to safety and security should be displayed in local languages. An appropriate security system must be in place to control all access routes to the site.

16.12.16 Impacts on Occupational Health and Safety

There is a tendency for the construction sector to be unregulated with respect to occupational health and safety. Additionally, unskilled and even some skilled construction workers may be illiterate and not necessarily informed or familiar with the protective measures to be adopted during work.

Mitigation

The contractors will need to carry out risk assessments and then develop site and Project specific Health and Safety Management Plans to prevent accidents, injuries and work-related diseases.

16.12.17 Impacts on Resources

Construction workers will need their daily supplies in the Project Area. This could potentially negatively affect the existing resource base and cost for firewood, food, goods, water and fish as well as create considerable amounts of waste. Both community members and construction workers will be affected by resource constraints and changing prices and are considered sensitive socio-economic receptors, because of their limited purchasing power and state of poverty which could be affected by these impacts. These impacts are considered to be negative and of minor magnitude.

Mitigation

Mitigation measures will be needed to ensure that the Project site is managed in a manner that is socially responsible and reflect sound environmental management practices. With respect to resource use, the Contractors will be expected to develop a plan and budget for providing workers with fuel for cooking and heating, water for cooking and cleaning, food supplies, and hygienic sanitation facilities for collecting and disposing rubbish, including construction waste.

16.12.18 Impacts on Cultural Heritage and Archaeology

No site of archaeological and historical importance has been identified in the Project Site. Some carving on stones were found near the powerhouse site regarding the incident of 2010 landslide but these carvings are outside the Project construction area.

Mitigation

Appropriate community relations have to be maintained for social respect between the local people and labor coming from other parts of the country.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.12.18.1 Water Pollution

Heavy machinery and equipment will be used during construction and operational phases of the project with huge quantity of explosives for blasting of rocks. Resultantly heaps of leftovers of explosives, grease, chemicals, lubricants, and other harmful materials will be produced on daily basis. These pollutants through run off rain water enter into the lake and river course increase toxicity of water causing rapid destruction of fish population and riverin ecology.

16.12.18.2 Fish Migration

Fish usually migrate from one place to another for search of food, shelter and spawning/breeding. Due to construction of the Project fish migration might be affect up to some extent.

Mitigation

Rapid mechanism of dispose-off of such kinds of hazardous materials will be required on urgency basis by dumping the extracted hazardous materials selecting safe landfill areas away from the main river course and its watershed, so that contaminated water in form of runoff could not enter directly into the main course.

Land sliding and soil erosion are also the main factor to contribute silt load on river bed manifold causing damage to resting and nesting grounds of fishes. Construction of protective walls and gabions at certain points to make sure the stoppage of sliding debris. Plantation and vegetation cover can also be helpful for slope stabilization. Plants, herbs and shrubs reduce the level of pollution and toxicity at a great extent as bio-filter and carbon suckers.

- Fish screening system should be developed so that fish may not be trap at intake, penstock pipe or channel.
- Sewage water treatment discharged from all labour camps and toilet facilities must be treated before disposal into the river.
- Tanks of fuel, oil and other liquids to be placed quite distant from any water body.
- Washing of vehicles or other machinery in the river or nullah is to be strictly prohibited.
- Oil changes for engines and other machinery to be only allowed in workshops.
- All vehicle and machinery to be maintained properly in order to avoid any leakages

16.12.18.3 Impacts on Power

The most significant impact of the Project will be the power generation as the Region is presently facing acute shortage of power. The power generating capacity of the Project is estimated as 54 MW, which is enough to remove the power shortage from the area. The power generated will help to establish new industries to boost commercial activities and to enhance job opportunities in the valley. Electricity generation impacts are considered to be most significant positive impact of the Project.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.13 CONFIDENCE BUILDING MEASURES (CBM)

People of Hunza are well educated and support development of projects, especially when it comes to power projects. However, in addition to satisfying the needs and requirements of locals, certain measures shall be taken in the form of CBM. During the social survey of the region, it was desired by the local communities to provide facilities where they could play sports and organize sporting events. For the said facility. Land would be acquired by the amount kept near Karimabad and Ganish for CBM, further infrastructure development can be developed with the help of involvement of NGOs.

16.14 ENVIRONMENTAL MANAGEMENT AND MONITORING PLAN

This section of the ESIA report provides an overall approach for managing and monitoring the environmental and social issues raised by the construction and operation of the ALHPP .The objective is to provide an overall frame work for implementing the mitigation measures that adequately address the identified adverse impacts and also the enhancements for predicted positive impacts. In addition, the items that require monitoring of the environment are also identified. All of these measures are to be put into a coherent Environmental Management and Monitoring Plan (EMMP), complete with the institutional arrangements and resources required to successfully implement the required actions.

The main objectives of an EMMP areas under:

- Provide the details of the Project impacts, along with the proposed mitigation and enhancement measures.
- Define the roles and responsibilities of the Project stakeholders, including the Project proponent, contractor, supervisory consultants and other key players.
- Identify the training requirements needed for the key role players in order for them to effectively implement the EMMP.
- Provide a mechanism in the form of an environmental monitoring program, that outlines which key parameters (both for the natural and social environment) will need to be monitored and the frequency that each of these has to be carried out.
- The objective is to ensure that mitigation measures are being effective in keeping environmental conditions within prescribed limits and if they are not, then making sure that there is an effective response mechanism that allows corrective action to be implemented.

16.15 MITIGATION MANAGEMENT MATRIX

The Mitigation Management Matrix (MMM), a preliminary out line is considered to be one of the main elements of the EMMP. The MMM shall be prepared during detailed design keeping in view the required functions and responsibilities and is to be used as the management tool for the implementation of mitigation measures. The mitigation management matrix should include:

- The required mitigation measures recommended in the ESIA Report.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Identification of the person or institution/organization directly responsible for adhering to or executing the required mitigation measures.

- The person or institution/organization responsible for ensuring and monitoring adherence to the mitigation measures.

- The parameters that will be monitored to ensure compliance with environmental standards and also with the requirements and objectives of the mitigation measures.

- The timing at which the mitigation or monitoring has to be carried out.

16.16 MANAGEMENT OF DIRECT CONSTRUCTION IMPACTS

Construction programs and management of construction impacts shall be included by drafting appropriate environmental management clauses into the construction contracts. Once a master check list of direct construction impact issues has been finalized then a monitoring checklist can be created for use by the supervising engineers during the construction period. It is crucial to clearly define the responsibilities of each of the parties in the construction works (contractors, supervisors and the Project Proponent).

16.17 SITE RESTORATION PLAN

The main areas that will require site restoration include the main construction site area, workers' accommodation sites, land used for vehicle and material workshops and stores along with material excavation and storage areas and temporary access roads and tracks. These areas will need to be restored to their original condition as far as possible and where there has been significant change then landscaped to fit with the surrounding area. The restoration work includes the removal of all temporary construction works and materials, followed by the landscaping and planting of the areas, including provision of adequate surface drainage to ensure that there will be no erosion and particularly sedimentation into the reservoir. The following procedures will be adopted for the restoration of the site:

- All temporary constructions built for the site development will be removed.

- Areas used for construction camps will be restored to their previous condition as far as is possible and where this is not then appropriately landscaped and planted to an agreed plan.

- All toxic and hazardous chemicals and materials will be totally removed from the site followed by treatment and environmentally appropriate disposal.

- During the construction program efforts will be made to minimize the risk of oil and chemical spills and an effective clean-up program should be in place to remove these as soon as they happen.

- All debris from construction activities should be removed from the site and appropriately separated, reused, recycled and composted with the residual material appropriately incinerated.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- All redundant fencing and gates will be removed and excavated pits will be appropriately backfilled.

16.18 RESERVOIR MANAGEMENT PLAN

Reservoir area will need to be managed during both the construction and operation of the project. The risk of debris entering the intakes also has to be considered. Once a clear idea of the construction program has been agreed then an appropriate reservoir management plan can be drawn up. This should also include the fisheries development plan for the reservoir, along with a recreation and tourism management program for the area.

The reservoir management plan will also have to consider the need for upstream catch management measures in the watercourses that directly discharge into the reservoir, based upon the results of water quality monitoring that will be carried out. The quality of the reservoir water will also need to be monitored to ensure that there is not a buildup of nutrients that could cause problems with algal growth. If this should start to occur, then adequate measures will needtobetakentopreventnutrientloadedwaterfromflowingintothereservoir.

16.19 IMPACT MONITORING PROGRAM

16.19.1 Objectives of the Impact Monitoring Plan

The objective of the environmental monitoring activities to be carried out during the construction and operation stages of the project will be as follows:

- To monitor the actual project environmental impact on the physical, biological and socioeconomic indicators that will be selected to be appropriate for such work in order to compare appropriate indicators with the situation before the start of the Project.

- To provide information that will allow recommend mitigation measures to be drawn up for any unforeseen impact or where the adverse impact level exceeds that anticipated.

- Ensure compliance with legal regulatory requirements and also community obligations, including health and safety at both the construction and operational stages of the Project.

- Ensure the safe and environmentally sound disposal of excess construction materials, solid waste and effluents, along with the adequate management of noise and dust emissions.

The main objectives of environmental monitoring during the operation phase will be to:

- Appraise the adequacy of the ESIA with respect to the predicted long-term impacts of the project on the physical, biological and socio-economic environment of the area.

- Evaluate the effectiveness of the mitigation measures proposed in the EMMP and recommend any improvements in the EMMP if they are found to be required.

- Compile periodic incident and accident data to support analyses that will help to minimize future risks.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Monitor the survival rate of the proposed vegetation planting program and make appropriate proposals to ensure that balanced mixed age and species stands develop in the area that provide sustainable supplies of fruit, fuel- wood and fodder for the local population.

16.19.2 Monitoring Strategy

All the compliance monitoring will be executed by the Contractor during the construction stage of the Project to ensure that they operate according to the regulatory framework. Supervision of the compliance environmental monitoring work during the construction stage will be carried out by the Supervisory/Management Consultants(SC).

16.19.3 Monitoring Parameters and Frequency

I. Natural Environment

For the physical environment the following parameters will need to be regularly monitored both before and during construction:

- Ambient air quality (mainly NOx, Sox and CO)
- Batching and crushing plant emissions (smoke, dusted.) during operation
- Ambient noise levels
- Water quality (drinking, surface and groundwater), for both chemical composition and also sediment

II. Socio-Economic Environment

The impacts on the socio-economic environment will be monitored by the SC using changes in house hold economic livelihoods as a major indicator in the longer term. Other key aspects that will need to be monitored include environmental and community health, safety issues, employment availability and generation, along with physical mobility and access, especially for women. At the construction stage of the Project the Supervisory Consultant will maintain a Social Complaints Register. This is an open public document that allows anybody to register a complaint which must then be thoroughly investigated and a judgment made as to its justification and the action need to address the issue.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

16.20 CONSTITUTION OFPROJECTENVIRONMENT MANAGEMENT COMMITTEE

Sr. No.	Agency	Representative	Status
1	WAPDA	Project Director	Chairman
2	Government of Gilgit-Baltistan	DC/ AC (Concerned)	Member
3	Consultant	Resident Engineer	Member
4	Main Contractor	Designated Engineer	Member
5	Environment Department	Director, EPA Gilgit-Baltistan Representative	Member
6	Local Government	Chairman District Council	Member
7	NGO	Representatives of two functional NGOs of the Region	Member

16.21 LAND REQUIREMENTS FOR THE PROJECT

Resettlement, land requirements and acquisition for any Mega Project is a sensitive task, however, for this Project these issues are not as critical as in other projects. Attabad Lake was formed in 2010 as a result of a natural disaster and it still recovers about 4.5 km2 of land which includes lands of Ainabad, Shishkat, Gulmit and Gulkin. Shishkat, Gulmit and Gulkin were partly damaged but Ainabad was completely submerged.

Land will be acquired for mostly powerhouse site which includes land powerhouse, switchyard, Project colony and Project offices. Land at weir site is mostly riverine land and will be acquired from the government. Land required for the ALHPP is mentioned in the Table 16-8.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 16-8 Land Requirements for ALHPP

Sr. No.	Description	Town / Village	Land in Acres	Land in Kanals	Land Cost per Kanal (DC Rates)	Remarks
1	Powerhouse Side	Sarat	4	32	750,000	Community Land of Ganish Village
2	Weir and Associated Structures	Attabad	15	120	500,000	Mostly it is riverine land. Left Side of Hunza River is Community Land of Ganish Village and Right Side is Community Land of Attabad Village.
3	Access Roads to Sites	-	-	-	-	Old KKH will be repaired where available and new will be constructed where not available
4	Permanent Project Colony	Sarat	2.5	20	1,500,000	Community Land of Ganish Village
5	Transmission Line	Throughout the T.L route	As per site	As per site	Varies	Land for T.L will be acquired along the route
	Total		**21.5**	**172**

17 ECONOMIC AND FINANCIAL ANALYSIS

17.1 INTRODUCTION

Electricity is imperative to social, agriculture, industrial development and growth of any Region. Electricity and energy consumption is an important indicator of economic growth. While 83% of the population of Pakistan presently has access to electricity, per capita energy consumption is about 516 KWh/year in the year 2020 (IGCEP-2021,2030)

Pakistan is endowed with a hydro potential of about 60,159 MW, most of which located in the provinces of Khyber Pakhtunkhwa (KPK), Northern Areas (NA) and Azad Jammu and Kashmir (AJK).

This section deals with quantitative analysis of the economic and financial aspects of ALHPP

17.2 ECONOMIC ANALYSIS

17.2.1 Introduction

Economic justification of investment in capital intensive project depends upon three factors, firstly the need of the project, secondly technological options available and the most economic choice (least cost option) for the project and thirdly the project will provide an acceptable return to the national economy and fulfills the debt obligation. The process involved the assessment of project benefits and identification of project cost over the economic life of the project. The basic technique for comparing costs and benefits occurring in different periods is discounted to express them in a common value in one point taking into account time value of money. Economic viability of the project has been checked under two approaches i.e. Equivalent Thermal Approach and Consumer Surplus to Pay (WTP).

17.3 CUSTOM DUTY

No import charges and sales tax has been added. However, custom duty @ 5% on import of plant and equipment not manufactured locally on foreign exchange component of E&M equipment are added to the project. (Refer Hydel policy for Power Generation Projects, 2015).

17.4 INTEREST DURING CONSTRUCTION (IDC)

The interest during construction has been calculated @12.20% per annum on both local and foreign cost components.

17.5 EXCHANGE RATE

Since 1982, the value of the Pakistani Rupee has been worked out with the help a "managed float" linking it to a basket of currencies. It is recognized that conversion factors are sometimes used even when a currency is floating especially if restrictions exist on currency exchange. Based on the facts it is concluded that conversion factor should not be applied to the exchange rate. Prevailing interbank exchange rate of US$= Rs 157 has therefore been applied.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

17.6 OPERATION AND MAINTENANCE COST

The operation and maintenance cost of the Project has been assessed @ 1% per annum of the base cost during its 30 years of useful life.

17.7 AUTHORITY OVERHEADS

The authority overhead has been fixed @ 1.5% on Civil, E&M and Preliminary Cost.

17.8 ANNUAL RECURRING COST

Recurring costs refer to expenses that reappear over a period. The annual O&M cost and annual amortization costs have been taken in the annual recurring cost.

17.9 LOCAL ESCALATION

There are three measures to compute escalation. These are GDP deflator, consumer price index (CPI) and wholesale price Index (WPI). The GDP deflator is the ratio of nominal gross domestic product (GDP) in a given year to real GDP of the year. Since the GDP deflator is based on all goods produced in the economy and is used to measure inflation and escalating project costs, hence the same is proposed for escalation purpose. The future projections of inflation rate are made on the basis of historical trends and government policies to curtail inflation.

The State Bank of Pakistan is taking hard decision to control the inflation by tightening the monetary policy. The government of Pakistan has also taken measures like reducing the budget deficit and effective management of domestic food supplies to curtail the inflation in Pakistan. During the last two years GDP rates were abnormal which cannot be applied for up-dating of costs. Taking a realistic value in a real term inflation rate of 6.5% has been used in this project.

17.10 FOREIGN ESCALATION

The major share of project cost shall be incurred on importing hydro-mechanical equipment's. The foreign cost shall also be required to be escalated during the construction. Two indices are available to escalate foreign cost components during construction. The manufacturing unit value index (MUV) represent the escalation rate of seven industrialized countries. For foreign cost updating escalation rate of 2% has been used (World Bank web site).

17.11 ERECTION & COMMISSIONING, LC, INSURANCE & SECURITY COST

These items have been charged @ 5% on Civil, E&M and Preliminary cost.

Base Cost (Million Rs.)	
Local	14350.480
Foreign	5678.440
Total Base Cost	**20028.920**
Price Escalation of Local and Foreign	1000.537
Custom Duties	216.706
Total Financial Cost	**21246.163**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

17.12 ANNUAL O&M COSTS

The annual operation and maintenance cost has been estimated keeping in view the recent years, expenditures and salaries of the staff. The O&M cost @1% of the base cost comes to Rs. 200.289 million with transmission line which will be met through selling of energy of power plant

17.13 PROJECT BENEFITS AND ANALYSIS

The economic and financial analyses have been carried on the following two scenarios:

1. Financial Internal Rate of Interest (FIRR) with transmission line without Capital Development mechanism (CDM)

2. FIRR with transmission line with CDM benefits

17.14 FINANCIAL BENEFITS

- The Hydro Power Project is highly beneficial due to less unit cost and providing inexpensive electricity. It will also help in saving foreign exchange on import of fuel.

- The financial benefits over the project life of 30 years calculated on certain assumptions depict an (FIRR) as 19.27%, and 19.17% with and without CDM benefits respectively which makes the Project significantly viable.

- The generation cost is worked out to be Rs 5.67/kWh (3.61 US Cents) over the useful life of the project and cost per MW of installed capacity being Rs 393.447 Mill (US $ 2.506 Million) with transmission line is also very attractive to reflect the financial benefits of the Project.

17.15 ECONOMIC BENEFITS

The economic analysis of the Project has been carried out on the basis of benefits to the overall economy as a consequence of least cost optimal development of the hydropower potential in the country. For this purpose, the benefits from the proposed steam unit/combustion turbine plant with (CDM) have been evaluated in term of costs foregone for providing an equivalent thermal generation.

The project will yield Internal Economic Rates of Return (IERR) of 22.54% & 22.36% with and without CDM benefits respectively. The benefit cost ratios come to 1.56:1, and 1.55:1, at 12% discount rate with and without CDM benefits respectively which also reflect the economic viability of the proposed Project.

17.16 SOCIAL BENEFITS

The Project with an installed capacity of 54 MW will generate 373.69 GWh of electricity annually which will assist in meeting power demand of the Hunza Region. The project will implement several programs that are designed to improve living standard of the area. These programs will provide improved health, education and infrastructure facilities while other programs will provide alternative source of income and create improved employment opportunities.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Moreover, the Project will avoid annual releases of about 149,476 tons of CO^2 from an equivalent thermal plant which have a corresponding reduction in atmospheric pollution.

The revenues of would increase due to direct and indirect taxation, duties and levies on the production of goods and services that will arise from the power generation within the Project Area as well as from the electricity duty collected by the Federal Government, Government of Baluchistan or any other Government agency.

The hydel generation plays an important role in the country's economy due to utilization of indigenous energy resources, in reducing load shedding and saving of foreign exchange required to import furnace oil.

17.17 BENEFITS OF THE PROJECT

17.17.1 Quantifiable Benefits

ALHPP would be constructed at Attabad using existing infrastructure. It will provide inexpensive electricity of about 373.69 GWh annually to the National Grid. The total installed capacity of the Project is 54 MW. It has no adverse impacts on the local environment, on the other hand it will help to reduce emissions as compared to a thermal Project. There are many benefits associated with the construction of hydroelectric power generating facility. These benefits include:

- Power will be produced from a renewable resource instead of depleting reserves of the country.
- Harmful by-products such as SO_2, NO_2, and CO_2, etc. are not produced by hydropower as with other fossil fuel sources.
- It will increase the regional power grid stability, reliability and availability.
- Local socio- economic benefits as a result of the construction, operation and maintenance of the facility.
- Multi-use of the water resource thus maximizing the intrinsic value of the overall facility.

17.17.2 Non-Quantifiable Benefits

The hydel project needs extensive civil works and can create significant number of job opportunities for engineers, technicians, skilled and unskilled labour during execution and operation of the project. The project is envisaged to bring economic uplift activities of far-reaching effects in the project area particularly electrification. Construction of ALHPP will have direct and indirect benefits for the local area. It will create new employment and job opportunities during construction and operation stages.

The Project will provide incentive for the establishment of small and medium size industry based on local raw material, creating gainful employment opportunities to the increasing work force. This will further help in alleviating disguised unemployment in agriculture sector. Providing basic infrastructural facility of electricity in rural areas goes a long way in checking large scale migration of rural labour force to urban centers.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Higher per capita disposable income would create more opportunities, improved health and education facilities. It would provide incentives to the work force to live near their homes and tendency to migrate to main urban centers would be reduced. In brief, it is envisaged that providing one of the basic infrastructure facilities of electricity at a suitable scale would usher in a continuous prosperity as well as economic emancipation by utilization of indigenous resources of land, labour and capital.

The revenues of the government would increase due to levies and taxes on the production of goods and services which would be a consequence of the electrification of the area as well as from electricity duty due to additional sale of power. Besides, the annual payment of interest charges to the federal government / loaning agency would be a substantial amount.

17.18 CLEAN DEVELOPMENT MECHANISM (CDM) BENEFITS

The CDM is an emission reduction (ER) trading agreement under the Kyoto Protocol between two countries, where greenhouse gas emission is reduced in a non-annex country and transferred to another country. Under the Kyoto Protocol

Pakistan deposited its intent of accession to the Kyoto Protocol in the UN Secretariat on 11 January 2005.To become eligible for CDM Projects, an operational strategy was developed to fulfill requirements of establishing a designated national authority (DNA) and ensuring transparent, participatory and effective management of CDM process in the country. Carbon Credits are applicable in certain cases of hydroelectric projects, where a demonstrable reduction in greenhouse gas emissions can be claimed as result of the project.

In order to qualify a project has to cross a number of barriers; in particular, by providing additionally measure of benefits that the project brings that would not have been available in its absence and quantifying the benefits in terms of a voided emissions. Once credits are confirmed, it is necessary to trade them through one of the carbon funds to convert into hard currency revenue from the start of the operation.

Recently a number of international organizations such as Asian Development Bank (ADB) have established a means of purchasing (CERs) units. The ADB also offer technical support to prospective developments for taking the necessary steps to be able to benefit from CDM. Unit can be traded in the open market on exchanging.

For the purposes of this analysis it is assumed that 373.69 GWh generated annually by this project will displace about 149,476 ton of CO^2 at 0.40 kg/kWh. One ton of CO2 corresponds to CER which is currently valued about 1.5 US$. Therefore, the CDM benefits worth will be 29.921 million Pak Rs per annum:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 17-1 Estimate of Annual CDM Benefits

Description	Unit	Value
Energy	GWh	373.69
CO_2 emission per kWh	Kg	0.4
CO_2 emission per GWh	Tons	400
Project CO_2 Emission	Million Tons	0.149476
CO_2 emission per Ton	US$	1.5
Project CDM Benefits	US$	0.2242
Project CDM Benefits	M.Rs	35.20
Benefits attributed to the Project	M.Rs	29.921

17.19 FINANCIAL ANALYSIS

The Project with an installed capacity of 54 MW will generate 373.69 GWh of electricity annually which will assist in meeting power demand of the country and will help in reduction of load shedding though insignificant. The project will generate revenue of Rs 5037.462 million and Rs 5007.541 million with and without CDM benefits annually at full operation. The Internal Financial Rates of Return (IFRR) 19.27% and 19.17% with and without CDM benefits respectively are shown in Tables-17-2 to 17-3.

17.19.1 Unit Cost Analysis

The cost per kWh of energy generated has been estimated by dividing average annual recurring cost with annual generation of the Project. The average annual recurring cost is arrived at by amortizing the total financial cost of Rs 21246.163 Million (Local Rs 15360.187 million and foreign Rs. 5885.975 million) inclusive of escalation, custom duty and IDC at an interest rate of 12.20% for both local and foreign components for 20 years and levelized over 30 years. Annual O&M costs with transmission line of Rs 200.289 Million has also been included. The Project generation cost with transmission line per kWh and cost per MW of installed capacity are shown in Table-17-4.

17.19.2 Breakeven Point (BEP)

BEP required to recover the recurring expenditure (Operating costs + Debt + Interest obligations). The breakeven production BEP is a production which determines the number of unit of energy volume of the project is 136.45 GWh of energy which is considerably less than the annual production of 373.69 GWh.

17.19.3 Payback Period

The payback period of the project are 5 years

17.19.4 Fuel Price

The scarcity of fossil, i.e. oil and gas for power generation demanded the development of renewable energy resources. Natural gas resources are depleting in Pakistan, which require from other countries, such as Dubai, Qatar, and Iran. The estimation of natural gas price to calculate the fuel cost per kWh of OCGT is cumbersome due to uncertainties in its availability. The price estimation further becomes complex with the depletion of indigenous natural gas reserves. Alternatively, re-gasification carryout from import of Liquefied Natural Gas (LNG) from Qatar is underway. Energy cost of thermal equivalent plants will be used.

The price of Qatar LNG has not yet been decided as such, LNG Price indicated in World Bank Commodities Data will be used to calculate the fuel price of the thermal plants. Average monthly price of LNG Japan is 5.98 $/mm Btu and after including shipping and re-gasification charges of 1.5 $/mm Btu, its comes to 7.48 $/mm Btu.AS per calculation depicted in Table 17-5

Table 17-5 Fuel Price kWh

Sr.	Description	Unit	
1	LNG Cost	$ mm btu	5.98
2	Shipping and Regasification	$ mm btu	1.50
3	LNG Cost (Fob)	$ mm btu	7.48
4	Heat Rate	btu kWh	6824
5	Fuel Cost	Cent/kWh	5.10
6	Fuel Cost	Rs.	8.42

17.20 ECONOMIC ANALYSIS

The economic analysis of the Project has been carried out on the basis of benefits to the overall economy as a consequence of least cost optimal development of the hydropower potential in the country. For this purpose, the benefits from the proposed steam unit/combustion turbine plant have been evaluated in terms of costs foregone for providing an equivalent generation.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The economic analysis is based on the following assumptions and summarized below:

DESCRIPTION		UNIT	OIL-FIRED
1.	Capital Cost/KW*	Rs	157000
2.	Plant Factor	%	80
3	O&M Cost @operated)	%	3.0
4.	Fuel Cost/KWh** Financial	Rs	8.42
5	Fuel cost / KWh: Economic	Rs	7.58

Source: Commodity price data world bank.

Results of economic analysis i.e. IERR with and without CDM benefits are calculated as 22.54%, & 22.36%. Detailed economic analyses are given in Tables-17-8 to 17.-9.

17.21 SHADOW PRICING

The economic analysis of the project requires that all costs and benefits must be evaluated at prices within the economy which reflect their real worth. Major inputs into the scheme of economic analysis do not necessarily reflect their true opportunity cost to the economy because of distortions in market prices. Like many other developing countries, the prices of goods and services are distorted by subsidies and taxes in Pakistan too.

The rate of foreign exchange has differed from its true opportunity cost., the price of labour in most of sector has generally been higher than its true opportunity cost. Shadow pricing has, therefore, been used to find out true opportunity cost of capital as well as other inputs to determine the economic cost of this project to the national economy.

17.22 COST OF CAPITAL

Shadow price of capital is defined as the opportunity cost of funds withdrawn from other uses and is considered equal to marginal cost of capital in the economy of Pakistan. The World Bank has used 10% discount rate for rural electrification projects and 12% by Planning Commission of Pakistan for economic evaluation of public sector projects followed by a study of Harvard Advisory Group on opportunity cost of capital. Accordingly, costs and benefits have been discounted @ 12% for the assessment of economic feasibility of the project.

17.23 COST OF LABOUR

In cases where there is significant unemployment and under-employment in a local economy shadow wage rates for labour should be used which are considerably lower than actual wages paid. The objective in economic analysis is to use the opportunity cost as an alternative application. In Pakistan the situation is one of under-employment for unskilled labour rather than full employment since there is labour shortages in rural areas in sowing and harvesting seasons. There is no employment problem for skilled labour as there are sufficient opportunities locally and in nearby oil producing countries.

Therefore, shadow wage rates of 1.00 and 0.75 for skilled and unskilled labour respectively, have been used for deriving the economic cost The economic cost of labour has been determined by applying shadow wage factors to the total labour cost which is equivalent to 38%

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

of the local cost of the project with 40% & 60% as skilled and unskilled labour components, respectively.

17.24 COST OF MATERIAL

Most of the material inputs for the project, i.e., steel, cement etc, are transported to the project site involving high freight expenditures. It is, therefore, assumed that shadow rate for material may be used as 0.91.

The results of shadow conversion factors have been applied to various components of project costs to derive adjusted economic costs

Table 17-6 Derivation of Standard Conversion Factor

17.25 ECONOMIC COST

The economic costs are derived by converting financial cost with adjustments for direct transfer payments like taxes, subsidies and interest (transfer payments) during construction, besides adjustments for distortions in the market prices of traded and untraded goods used in the project works. For this study also economic costs of the project have been derived by removing transfer payments in addition to adjustment of cost of labour and material with appropriate shadow conversion factors. The economic costs of the project thus derived have been used in economic evaluation and given in detailed calculations are as follows:

17.26 DERIVATION OF THERMAL EQUIVALENCE

The Feasibility has been assessed on the assumption that in the absence of hydel generation, an equivalent thermal generation plant would be required to produce equivalent amount of energy per annum. A comparative study has, therefore, been made and costs calculated on the basis of providing an equivalent quantum of generation from the steam plant using furnace oil described as economic benefits

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

17.27 EMPLOYMENT ANALYSIS

The project will help in providing employment to the inhabitants of the local area and play an important role in the country's economy. The project will also help in improving/enhance the socio-economic settings of the area.

17.28 SENSITIVITY ANALYSIS

Although the project has shown financial viability with higher rates of return than the weighted cost of capital even then the project is susceptible to different kind of adverse circumstances like cost over-run, delay in construction and decrease in benefits. The financially viability of the project has, therefore, been assessed against 10% decrease in benefits, 20% cost overrun, as well as combined impact of both the variations to see if the project remains financially viable.

Tables-17-10 to 17-11 give risk/sensitivity analysis on the following assumptions:

I. 10% reduction in sale price.

II. 20% cost over-run.

III. Combined effect of above

17.29 CONCLUSION

The Project is economically, financially and socially viable in addition to its technology viability hence recommended for implementation.

18 CONCLUSIONS AND RECOMMENDATION

Attabad Lake Hydropower Project (ALHPP) is a Run off River peaking scheme on Hunza River in Hunza Region at Attabad Lake. Attabad Lake is located about 120 km from Gilgit on the Hunza River along Karakorum Highway and 735 km from Federal Capital Islamabad. The Project is planned to develop the reach of river 2.5 km downstream of Attabad Lake with an installed capacity of 54 MW to generate mean annual electricity of 374 GWh.

The Feasibility Study of ALHPP has been carried out with due consideration of intensive field investigations (topographic and hydrographic survey, subsoil investigations and geological mapping), Socio-Economic and Environmental Survey.

With landslide on Hunza River on January 4, 2010, Attabad Lake was created. The natural head available from Lake to 2.5 km downstream and perennial flows of Hunza River attract to develop the indigenous hydroelectric resource. The slided mass have been investigated to propose the overflow weir/sediment flushing channel for flood evacuation, sediment flushing and desing discharge through headrace tunnel.

Detailed topographic survey and geological mapping have been carried for all major structures like overflow weir/ungated spillway, sediment flushing channel, intake, low pressure tunnel, and power house area. For reservoir area, hydrographic survey have been carried out six (6) borehole have been drilled at important sturctures location with total drilling depth of 400m.

For social and environmental aspects, detail survey has been conducted in the field and maps with DEM have been prepared to cover the Project Area details.

Power and energy potential at the site have been estimated on average 10-daily basis using time series data from 1966 to 2015. Keeping in view historic data, optimized design discharge of 60 m^3/s has been selected that could be made available during peak hours throughout the year . The available head across the hydropower facility has been estimated as 106 m with the consideration of upstream and downstream water level variation. The estimated mean annual energy is 374 Gwh and plant factor is 79.0%.

Overflow weir/ ungated spillway, sediment flushing channel/under sluices, intake, low pressure tunnel, surge tank and powerhouse, main dam and dykes / embankments have been designed based on field investigations to accommodate the flood and reservoir variation from 2014 m a.s.l to 2021 m a.s.l.

The cost estimate for the Project has been prepared using bill of quantities (BOQ) and costs for Infrastructure development, Preliminaries and Environmental Mitigation, Civil, Hydro-mechanical, Electrical, etc. Major Civil Works items such as rock excavation quantities, slope stability by benching concrete and grouting works, etc. have been estimated as Rs.21.246 million (US$ 135.32 million).

The Project is found economically and financially feasible. The calculated economic internal rate of return (EIRR) is above 22.36% (the assumed opportunity cost of capital in Pakistan) and the financial internal rate of return (FIRR) comes out to be 19.17%.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

ALHPP is found to be technically feasible, economically viable and environmentally acceptable and will fulfill electricity needs particularly for Hunza City and in general for Hunza, Gilgit and Ghizar Regions. Therefore recommended for implementation at earliest.

LEGEND (GEOLOGY)

SOIL UNITS:

- ABGM — Angular boulders and gravel with sand and appreciable amount of fines.
- RBGM — Rounded boulders and gravel with sand and appreciable amount of fines.
- CT — Cultivated Terrace.
- Mor — Morainic Material
- CS — Clayey Silt.

ROCK UNITS:

- G.Dio — Granodiorite
- G.Dio + GGn — Granodiorite + Granitic Gneiss.
- BR — Fault Breccia.
- Dip and Strike of joint sets in rock.
- Dip and Strike of foliation.
- Active slide.
- Shear zone.
- Fault
- BH — Bore Hole.
- TP — Test Pit.

ATTABAD LAKE HYDROPOWER PROJECT

IMPLEMENTATION SCHEDULE

Activity ID	Activity Name	Original Duration	Start	Finish
Attabad Lake HPP		1519	03-May-21	30-Jun-25
Pre-Construction Phase		460	03-May-21	06-Aug-22
A1000	Approval of PC-I	90	03-May-21	01-Aug-21
A1010	Procurement of Consultants	90	03-Aug-21	01-Nov-21
A1020	Review of F.S and Preparation of EPC Tender Documents	120	08-Nov-21	08-Mar-22
A1030	Procurement of EPC Contractor & Award of Contract	150	09-Mar-22	06-Aug-22
A1040	Land Acquisition	270	01-Nov-21	29-Jul-22
Construction Phase		1045	20-Aug-22	30-Jun-25
A1050	Mobilization & Site Installations	60	20-Aug-22	19-Oct-22
A1060	Detailed Engineering Design of Civil & E&M Works	890	20-Sep-22	26-Feb-25
A1070	Additional Survey & Investigations	90	04-Oct-22	02-Jan-23
A1080	Access Roads to Main Works Sites	90	04-Oct-22	02-Jan-23
A1160	Offices and Residential Complex	120	03-Mar-23	01-Jul-23
Construction of Main Works		884	28-Jan-23	30-Jun-25
Care and Handling of Water		660	03-Mar-23	22-Dec-24
A1700	Construction of Coffer Dam (Stage-I)	45	03-Mar-23	17-Apr-23
A1710	Dismantling of Coffer Dam (Stage-I)	15	02-Nov-23	17-Nov-23
A1720	Construction of Coffer Dam (Stage-II)	40	02-Nov-23	12-Dec-23
A1730	Dismantling of Coffer Dam (Stage-II)	15	07-Dec-24	22-Dec-24
Sediment Flushing Channel		243	03-Mar-23	01-Nov-23
A1090	Left Bank Slope Stabilization	180	03-Mar-23	30-Aug-23
A1100	Excavation	70	17-Apr-23	26-Jun-23
A1110	Dewatering	145	22-Apr-23	14-Sep-23
A1130	Fixing of Reinfocement & Concreting	100	01-Jun-23	09-Sep-23
A1140	Backfilling & Compaction	20	25-Aug-23	14-Sep-23
A1150	Installation of Gates	60	02-Sep-23	01-Nov-23
Power Intake		350	08-Nov-23	23-Oct-24
A1260	Rock Excavation & Rock Supports	55	08-Nov-23	02-Jan-24
A1280	Fixing of Reinforcement & Concreting	165	02-Mar-24	14-Aug-24
A1290	Backfilling & Compaction	30	25-Jul-24	24-Aug-24
A1300	Installation of Gantry Crane, Intake Trashrack & Gates	75	25-Jul-24	08-Oct-24
A1500	Installation of Trashrack Cleaning Machine	45	08-Sep-24	23-Oct-24
Overflow Weir / Ungated Spillway		275	06-Mar-24	06-Dec-24
A1190	Right Bank Slope Stabilization	150	06-Mar-24	03-Aug-24
A1200	Dewatering	160	05-Apr-24	12-Sep-24
A1210	Excavation	135	20-Apr-24	02-Sep-24
A1230	Fixing of Reinforcement & Concreting	180	09-Jun-24	06-Dec-24
A1240	Backfilling & Compaction	25	11-Nov-24	06-Dec-24
A1370	Stone Apron U/s & D/s	25	11-Nov-24	06-Dec-24
Adit / Access Tunnel		150	28-Jan-23	27-Jun-23
A1310	Excavation & Rock Supports of Access Tunnel near Power Intake	150	28-Jan-23	27-Jun-23
A1320	Excavation & Rock Supports of Access Tunnel near Surge Tank	67	28-Jan-23	05-Apr-23
Low Pressure Headrace Tunnel		756	05-Apr-23	30-Apr-25
A1330	Excavation & Rock Support from Adit near Surge Tank	533	05-Apr-23	19-Sep-24
A1340	Excavation & Rock Support from Adit near Power Intake	234	27-Jun-23	16-Feb-24
A1660	Concrete Lining	230	12-Sep-24	30-Apr-25
Surge Tank		360	03-Mar-24	26-Feb-25
A1350	Excavation & Rock Supports	210	03-Mar-24	29-Sep-24
A1360	Concrete Lining	150	29-Sep-24	26-Feb-25
Penstock		300	02-Mar-24	27-Dec-24
A1380	Excavation of Trench	60	02-Mar-24	01-May-24
A1390	Erection of Penstock	225	02-May-24	13-Dec-24

1 INTRODUCTION

1.1 GENERAL

Attabad Lake Hydro Power Project (ALHPP) is proposed on Hunza River, a left tributary of Gilgit River. A large slide occurred on January 4, 2010 from right side slope of Attabad chocked the Hunza River. The total height of the slide as estimated by GSP (Geological Survey of Pakistan) was about 100 m and the blocked length of river was about 2 km that destroyed 1.3 km of Karakorum Highway (KKH) (ISSMGE Bulletin: Volume 4, Issue 3 Page 21). WAPDA Authority planned to utilize the potential of hydropower due to this lake. Firstly, Govt. of GB carried out Feasibility Study by engaging Local Consultants. The study was deficient in many aspects including geotechnical investigations, laboratory testing, layout planning, pros and cons of sliding, Neo-tectonic study and environmental issues. Therefore Govt. of GB requested WAPDA to carryout Feasibility Study again and Hydro Planning Organization (HPO), WAPDA updated the Feasibility Study.

The HPO, WAPDA entrusted to carry out the Feasibility Study of ALHPP. During the detailed analysis and investigations, it is estimated that Lake potential of 0.1MAF (125 Mm^3) can be utilized to generate about 54 MW of electricity.The coordinates of weir site are 484036.834 m E and 4018143.837 m N with mean bed elevation about 2368 m a s l **(DRW No: AFS- WR - 403)**

The proposed weir site is located about 20 km upstream of Aliabad (Central Hunza), near Attabad village, District Hunza. The site is accessible by metaled road from Gilgit, the capital of GB. From Islamabad, the site is reachable through Karakorum Highway (KKH) by covering about 750 km. It is also accessible through PIA airplane from Islamabad to Gilgit and there on to Hunza via Karakurum Highway **(DRW No: AFS- GN- 102)**. Recently PIA operated direct flights from Lahore and Karachi to Gilgit.

Geologically the site is located in Karakorum Block further north of Main Karakorum Thrust (MKT). The Karakorum Block consists of Sedimentary, Metasedimentary, Igneous as well as Metamorphic rock, throughout its extension from Karakorum Fault in the east, Chaman and Herat Fault in west (Zanchi 1993) ranging in age from Precambrian to Cretaceous. The overburden material, consist mainly of Angular Boulder Gravel with Sand and appreciable amount of fines (ABGM) and Rounded Boulder Gravels with Sand and appreciable amount of fines (RBGM). The talus deposits are main constituents of ABGM and well developed mostly in Shamshal valley and along Hunza River in upstream reaches. There are many evidences (the deposition of clayey silt along both banks of Hunza River) along the road indicate that river might have chocked many times in recent past. Prior to Attabad slide, the slope failure occurred at Salamanabad in 1958 and chocked the Hunza River.

The topography and geological conditions present in this valley indicates that it is glacial originated valley modified later on by river system. There are many glaciers that feed the Hunza River, from south to north i.e. Hassanabad, Gulmit , Gulkin, Passu and Batura Glaciers, from right side and Shamshal Valley Glacier from left side. Morphologically the valley is lithological as well as structurally controlled. Weak lithology i.e. slates as well as fault system attribute for the development of present shape of the Hunza valley in upper reaches and near MKT.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

This report is mainly based on the annotations observed during geotechnical investigations carried out at ALHPP. The geological and geotechnical investigations include Surface Geological Mapping, Drilling and Test pits at weir site, sediment flushing channel/under sluice, headrace tunnel and powerhouse area, and identification of borrow area for construction material. Samples collected during geotechnical investigations have been tested to ascertain geotechnical properties at Central Material Testing Laboratory (CMTL), Lahore.

1.2 SCOPE OF WORK

During the Feasibility Study of ALHPP, HPO, WAPDA, has identified the deficiencies of geotechnical investigations in pervious Feasibility Study (FS) and carried out detailed geotechnical investigations for comprehensive FS at present. The layout plan was completely changed during present FS and investigation were conducted according to new layout. One of most important aspect is Neo-tectonic studies, because this area is affected by Attabad Slide in 2010. It is very important for the development of hydropower project in this area to develop the understanding of Neo-tectonic setting operating under regional tectonic forces for the stability and planning of the hydropower project. All the geotechnical data procured during geotechnical investigations have been utilized for foundation evaluation of all the structures of ALHPP.

1.3 OBJECTIVES

Main objectives are:

- Evaluation of the surface condition of rock mass i.e. shearing, fracturing, jointing, faulting, appropriately during surface geological mapping.
- To investigate the subsurface geological conditions by drilling at weir, sediment flushing channel/undersluice, tunnel and powerhouse area.
- Test pits have been carried out to explore the shallow subsurface conditions of different project structures.
- Core samples from different boreholes, selected and sent to CMTL to conduct testing, for design of different structures.
- Identification of borrow area for coarse as well as for fine aggregate. Samples from these areas were collected and sent to laboratory to carry out different tests for their suitability for construction as well as for rip rap material.

1.4 METHODOLOGY

These include:

- Collection of previous research on regional as well as on local geology, geomorphology and tectonics of Project Area.
- In-depth studies on GT sheets of the area after enlargement at scale of 1:10,000.
- Detailed topographical survey at scale of 1:1000 to study all the aspects of slided mass and slope area along both banks of the Hunza River.
- Detailed geological map of the Project Site using plane table , brunton compass, long range Topcon Total Station, used to mark the contacts among different lithological units as well as different soil units at geological map.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- During field visit keen concentration has been given to characterize the kinematics of fault where possible e.g. sense of fault (Strike and Dip), alignment and type of fault, dip direction and other associated characteristics.
- Total 400 m drilling consist of 6 boreholes have been drilled at weir site, sediment flushing channel/undersluice, tunnel and powerhouse area to observe the subsurface conditions. Drilling activity was executed by Drilling and Investigation Division (DID) of Hydro Planning Organization, WAPDA with Longyear as well as Acker Drilling rigs, from September to December 2020.
    - A total 10 test pits were excavated to explore the shallow subsurface conditions. Composite samples have been collected and sent to CMTL for testing.
    - Borrow areas for fine as well as for coarse aggregate has been identified. Samples from these areas have been collected and sent to laboratory for different testing, to check their suitability for construction work.

2 REGIONAL GEOLOGY

2.1 GENERAL

Information and data relating to regional geology of Project Area is taken from already published literature and research papers. The catchment area lies in Karakorum Block (KB) where snow covered peaks are quite common. The geological features in 40 km upstream and 50 km downstream of the Project Area have been studied in detail. In the Project Area many neo-tectonic features have been observed/recorded in the recent deposits which indicate that the regional tectonic forces are operating there.

The Project Area lies in the KB bounded in north by Central Pamir through Rushan Pshart Suture, in east by Karakorum Fault, in the west by Herat Fault and in south by Kohistan Island Arc (KIA) through Main Karakorum Thrust (MKT) (Pashkov & Shvol'man, 1979 & 1981). The KB have classified as a part of Gondwana land in pre-collision history. The rocks of KB have stratigraphic association with rocks of Indian Plate as indicated by Paleozoic to Mesozoic sequence of both plates. It is likely to be considered that Karakorum Micro Plate and Indian Plate were united till Mesozoic Era.

The stratigraphic sequence of the Karakorum Plate is metamorphic equivalent of Sedimentary Rock in Indian Plate shows that both plates have pre-collision similarities. Also the Karakorum Plate consists of sedimentary (well exposed is in Chitral along Mastuj River), Ignoeus rocks (Karakorum Batholith) and Metamorphic rock (slates, schist and marbles).

The rocks of KB include a thick sedimentary cover, which is mainly Paleozoic in the western termination and Permian to Cretaceous in the central and eastern area. In the Hunza valley, the cover consists of a thick pile of Permian-Cretaceous sediments cropping out north of the Karakorum Axial Batholith (KAB). It separates the sedimentary cover to the north, named North Karakorum terrain by Searl (1991), from high to low grade metamorphic present south of the KAB just north of the MKT.

2.2 STRATIGRAPHIC SEQUENCE

The area under study mostly includes part of the Northern Karakorum Terrain, which comprises intensively folded and thrusted sedimentary rocks with a very low metamorphic imprint, locally reaching low grade conditions (Zanchi,1993). The Lower Permian to Upper Cretaceous succession of the North Karakorum represents one of the few terrains which escaped strong metamorphism during the Indian-Eurasian collision, thus permitted a detailed reconstruction of its stratigraphic framework **(DWG No: AFS-GE-291).** Plutonic bodies mainly of mid-Cretaceous age intruded the sedimentary cover forming a discontinuous granitic belt developed about 100 km north of the KAB. Four main tectonic units have recognized in the Project Region (Gaetani et all., 1990). These include;

- Misgar Unit
- Sost Unit

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Gojal Unit
- Karakorum Axial Batholith (KAB)

The brief description of these units are given below;

2.2.1 Misgar Unit

This unit consists mostly of slates, with few intercalations of metacarbonate quartzite and black terrigenous slates, mostly exposed at the Northern part of the Project Area. In some areas, its thickness increases upto thousand meter. It is strongly folded with intensive development of slaty cleavage. The fold axes generally trend E-W upto the Khunjerab Pass, where they turn to NNW-SSE. The unit has low grade metamorphism indicated by chlorite, biotite, and muscovite. This unit is intruded by granitoide pluton in northern and eastern terrain having western extension upto Sost. This unit belongs to different stratigraphic formations of Paleozoic age.

The southern boundary of Misgar Unit is faulted with south vergent thrust plane, the northern fault stacking the Misgar Slate over Jurassic limestone and sandstones of Sost belt (Gaetani et al. 1990). Large recumbent folds present along the northern flank of the Chapursan valley suggest southward movement of Misgar Unit.

2.2.2 Sost Unit

It consists of grey to dark grey slates, meta-limestone, and quartzite. At places, it has dolomitic patches (Gojal Formation). Some sandstone beds with slate intercalations overlain by argillaceous limestone (Gircha Formation). Some sandstone, siltstone limestone and dolomites of Lupghar Formation, Panjshah Formation, Lashkargaz Formation of middle to late Permian age.

It comprises thick pile of folded and thrusted sheets forming in the whole antiformal stack, later disrupted by strike-slip faults. The unit is bounded by two major faults, the Upper Hunza Fault (Desio, 1979) to the south-east and the Northern Fault to the north. Complexity of the tectonic pattern often prevented the reconstruction of continuous stratigraphic successions, as in the Middle Late Jurassic sediments. Fold axes and fault striations along the main thrust surface generally indicate a N-S compression. The well-developed schistosity is defined by sericite, muscovite and fine grained biotite with occasional occurrence of epidote and chloritoid. This suggests that low grade condition of metamorphism with an important increase of temperature with respect to other thrust sheets of the Sost Unit. These shear zones are still poorly understood and may possibly be related to the eastward prosecution of Hunza Fault juxtaposing the Gircha Slates of Gojal Unit to analogues metasediments of Sost Unit. The stratigraphic succession present in the Sost Unit spans from Permian to Late Cretaceous.

2.2.3 Gojal Unit

This tectonostratigraphic unit was defined by Gaetani et al. (1990) and includes the sediments lying between the Karakorum Axial batholith and the Upper Hunza Fault (UHP). It is composed of two units, a terrigenous unit (Passu Slates) below and a calcerous-dolomitic unit above. In the lower Shamshal valley, dolomitic marbles terminate along a subvertical NS trending fault while southward this unit is intruded by KAB. Contact metapelites generally undeformed or

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

poorly deformed intrusive that grades into biotite, muscovite, and andalusite. Folds within the unit trend from NW-SE to NNW-SSE and are generally NE-facing. Thrust planes show the same trends and are NE-vergent, as in case of UHF.

2.2.4 Karakorum Axial Batholith (KAB)

The KAB crops out along the southern part of the study area, where two major plutonic complexes were recognized, the Hunza and Batura Units (Debon et al., 1987). The Hunza Unit consists in a huge plutonic unit extending for more than 250km, made up of medium grained granodioritic in composition, locally recrystallized. They represent a calc-alkaline association. Mafic enclaves of various sizes are abundant and a conspicuous network of Cenozoic leucocratic dykes is locally present.

The Batura Unit intrusive, spanning in age from Paleocene to Eocene, is mostly new, as well as the findings of plutonic bodies belonging to this unit in Upper Chapursan valley. The Batura Unit includes two main intrusives; The Kuk and Sarbzea Plutons.

The Kuk Pluton consists in pinkish, un-deformed and un-foliated granitoides of various grain size, locally with porphyritic, microgranular and rapakivi textures. The Sarbzea Pluton mainly differs from the Kuk Pluton by its very coarse to medium grained rocks, sometimes deformed.

2.2.5 Ganesh Formation

This Formation consists of pelite-psammite turbidite unit and overlying calc-pelite marble unit and are intercalated with each other. These units are metamorphosed up to upper amphibolite facies and therefore have well developed sheets of amphibolite. The Formation has well developed ruby and spinal. Different mines are also established in this unit as can be observed along road near Ganesh Bridge.

2.2.6 Hassanabad Granite

It is well exposed in the Lower Hunza valley and consists mainly of lower s-type granitoid-migmatite complex with metasedimentary enclaves. These garnet-tourmaline bearing two mica granitoids and migmatites are well exposed in Hasanabad Nullah and in Hunza valley along Hunza River.

2.2.7 Chalt Formation:

It consists of dark grey quartz biotite schist with subordinate quartz, marble and conglomerate. It is exposed along overturned anticline and faulted against Dumordo Formation. Permo-Carboniferous age is assigned to this Formation.

2.3 REGIONAL TECTONICS

Before the northward flight of the Indian Plate, small continental pieces (Cimmerids, i.e. Karakorum, Helmad , Hasha ocks etc) were broken up from the northern edge of Gondwana and welded with the southern edge of Eurasian Plate, consuming the old Tethey and opening the Neo Tethey, (Tapponnier, 1975, 1977; Molnar, 1977a).

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

In general, due to the subduction of the oceanic part of the Indian Plate beneath the Eurasian Plate, the Island Arc emerged in Middle Cretaceous age. The Arc Complex consists of Calc-Alkaline Plutonic Rocks mainly mafic in nature. The presence of Blue Schist Metamorphism in Swat and Shangla Area indicates the trench environment.

The collision of the Indian and Asian Plates has been described as a “head on” north-south collision (Shackleton and Ries, 1984). This is generally accepted by many workers to have occurred in Eocene times (55-40 Ma) (Powell, 1979; Klootwijk et al, 1979; Dewery et al, 1988; Treloar and Coward, 1991; Serrle et al, 1987, 1988). The terminal collision between Indian and Asian Plates is suggested to have occurred between 45-40 Ma (Molnar and Tapponnier, 1975; Klootwijk et al, 1985). It is generally agreed however, that by 55 Ma, the Kohistan Island Arc was already sutured to the Asian Plate, probably since the Late Cretaceous, forming the MKT Zone. This is confirmed by the presence of 85-80 Ma thermal event at this time (Treloar and Rex, 1990).

The rocks of Shyok Suture Zone are interpreted to represent the tectonised remainder of a marginal basin. The closure of the marginal basin occurred at the Eocene-Oligocene time boundary, and crustal shortening was responsible for generation of Neogene 2-mica granites of the Karakorum Plutonic complex and regional metamorphism of the Pangong Tso Group (V.C Thakur, D.K. Misra, 2007).

The collision between the Indian Plate and Kohistan Island Arc is recognized as when the Tethyan Ocean disappeared and the continental masses docked. Following features recognize the main arguments for the Eocene age of collision: -

- Sediments deposited on the northern margin of the Indian Plate being of Eocene age.
- Subduction of the oceanic crust stopping, as recognized by the end of calc-alkaline magnetism north of the Indus Suture.
- The blue schist facies are not developed along MKT zone showing the collisional belt.
- Slowing down of the Indian Plate motion, as recognized by magnetic anomalies.
- After collision, continued suturing occurred, associated with a 35˚ anticlockwise rotation of the Indian Plate relative to Eurasia. As a result of collision mighty mountain ranges of Himalayas were developed having Island Arc Sequence in the north.

There are some topographic observations about the Himalayas that were immediately noticeable:

- The general curvature of the mountain chain.
- The mass of high land behind the mountain belt (Tibetan Plateau)
- The lineament of the high peaks confined in a rather smaller area.

This seemingly simplified chain becomes very disturbed, with a complete loss of these features in the Northern Himalaya. The general curving of the Higher Himalayan Peaks and the suture around angles of some 180˚, is related to the structural anomalies that are present in Northwestern Himalaya: i.e. the syntaxes (Nanga Parbat Syntaxis, Hazara-Kashmir Syntaxis etc). These are absent in Central Himalaya. This shows that the collision between two Plates is

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

not a simpler phenomenon but there was a much greater extent of deformation to which the collision was accommodated. The accommodation was not constant, but suggested to be partitioned with different mechanisms occurring in different places of the orogenic belt.

Anticlock wise rotation of Mega Lhasa followed the Late Triassic docking of the Iranian Spur, using the later as pivot. The rotation was completed during the Middle Jurassic, when SE Pamir, Shaksgam and Karakorum joined the Qiangtang, more closely assembling Mega Lhasa as it approached the Asian margin (Maurizio Gaetani, 2007). The KB bounded in the east by Karakorum Fault, in the north by Rushan- Pshart Suture, in the west by Herat Fault and in south by Main MKT.

Structurally the KB is characterized by broad asymmetrical to tight, isoclinal folds which are commonly imbricated. A number of large regional scale thrust faults, e, g. the Tirchmir Fault, Reshun Fault, Baltit Fault, UHF, and Chapursan Fault and the MKT extends for a distance upto 100 km or more. The KB has undergone multiple deformation since the Cambrian. Parts of the KB have undergone at least four more deformations since the Kohistan-Karakorum collision from Paleocene to Pliocene.

After the collision, due to further northward subduction of the Indian Plate, still active 45mm/yr, the stresses were accommodated by the imbricate thrust faults from north to south (Treloar et al, 1989). The collisional history along with metamorphic events, trapped many clues between these fault systems. These are very useful to delineate the historic events and to unravel the movement of Indian Plate, collisional environment and modern deformational style.

2.4 REGIONAL FAULTS

The major regional faults of the region include, from north to south, the MKT, Main Mantle Thrust (MMT), Panjal Thrust (PT), Main Central Thrust (MCT), Main Boundary Thrust (MBT), Kashmir Boundary Thrust (KBT) / Himalayan Frontal Thrust (HFT) and Salt Range Thrust (SRT) **(DWG No: AFS-GE-292).**

Along with these regional faults, many local faults were developed to accommodate the regional stresses; these may be thrust fault or strike slip fault in nature. In most of the area many small scale strike slip faults are associated with the thrust faults to accommodate the deformation.

The general trend of these faults excluding MKT is predominantly east-west with change in trend due to syntaxial bends. The general descriptions of these major faults are given as follows: -

2.4.1 Karakorum Fault

Dextral Strike Slip fault of about 800 Km long bounds Western Tibet. The Karakorum Fault (KF) represents a much younger terrane boundary, juxtaposing rocks of the Ladakh and Saltoro Blocks to those of Karakorum terrane. U-Pb zircon age of leuco-granites intrusion shows that it is younger than 15 Ma old. Movement on the fault displaces the sequence approximately 200-250 Km to Southeastern Tibet where the regional rock sequence can be regained (Burtman et

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

al. 1963, Srimal 1983). It merges at the confluence defining a triple point and three blocks; the Ladakh Block to the south, Saltoro Block to the northwest, and the KB to the northeast.

A number of teleseismic events have occurred along the fault. Interpretation of seismic data from 1975 Kinnaur earthquake confirms right-lateral strike slip motion on this fault. Three events were recorded from Karakorum Fault Zone (KFZ) at the head of the Nubra valley, since 1980, recorded by portable seismic stations, established by International Karakorum Project (IKP). It is seismically an active fault.

2.4.2 Upper Hunza Fault

It is east west trending thrust fault that runs along the depression formed by the Chapursan and Upper Yarkhun valleys (Zanchi 1973, Kazmi 1979b, Gaetani ey al. 1995). In this region it runs parallel to the northern margin of the Karakorum Axial Batholith (KAB). Southeast of morkun (Upper Hunza) three teleseismic events of magnitude 5-7 and focal depth of less than 50 km have been recorded. These epicenters form a cluster very close to the mapped trace of the UHF. It means that the northern and western margins of the KAB is characterized by active zone of faulting along Upper Hunza-Reshun Fault zone.

2.4.3 Main Karakorum Thrust

The MKT is a low angle mega-shear with strike slip component, which on eastern side passes through Machlu in Hushe valley, Shigar valley, Zuhri Brook in Shyok valley and Chalt in Hunza valley extends westward through Ishkuman, Yasin and Shishi valleys **(DWG No: AFS-GE-292).**. Its general trend swings between east and - east-northeast at low to medium dips towards the north. It is believed that this Fault is seismically active.

2.4.4 Main Mantle Thrust

The MMT, which is aligned with the Nanga Parbat-Haramosh tectonic line on east, span an area of about 400 km through Diamir, Kohistan, Swat, Dir and Banjaur, before entering Afghanistan **(DWG No: AFS-GE-292).** The general trend of MMT is NE-SW. It is located along the contact of the mafic/calc-alkaline meta igneous rocks and the meta-sediments belonging to the Indo-Pakistan continental mass. Along this Megashear near Jijal village on Indus River (right bank), the igneous rocks have overthrusted the meta-sediments to the south over a 10-15 km wide zone. The thrust also manifests as the broad high topography of Kohistan relative to the Hazara adjacent to the south. In addition, numerous auxiliary fractures are developed and across the thrust frequent brecciation and mylonitization are also present along the contact. It is seismically active fault.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3 SITE GEOLOGY

3.1 GENERAL

The Project Area lies in KB north of MKT. It is V-shape valley, originated by glacier and modified later on by Hunza River. It is stratigraphically as well as structurally controlled. The second highest peak of the World K-2 lies in this Range. The rock units comprise granitoides with pellite and psammite sequence ranging in age from Paleozoic to Cretaceous age.

3.2 SURFACE GEOLOGICAL MAP

The surface geological mapping has been carried out at scale of 1:1000, consists of 16 topo-sheets prepared by Survey Division Peshawar, HPO, WAPDA. During the site visit at left and right side of the Hunza River, different rock units have been studied and marked on the map and presented as drawing **(DWG No: AFS-GE-293 to 312).** Different geological units marked on map are summarized below:

3.2.1 Lithological Units

3.2.1.1 Soil Units

The recent deposits are the most widely spread soil units overlies the bed rocks. The slopes are covered with overburden having variable thickness. Terrace deposits comprise mixtures of clay, sandy silt, boulders and gravel in various proportions. These units are mostly present in Aliabad, Karimabad, Nagar and Gojal **(DWG No: AFS-GE-293 to 312).**

The soil units present in the Project Area are described below: -

3.2.1.1.1 Angular Boulder Gravels with Sand and Appreciable Amount of Fines (ABGM)

Most of the slopes are covered by material comprising of ABGM. This is colluvial material broken from the rock units rolled down slope and settled at the foothill or along the slopes.

These deposits are mainly associated with crushed/brecciated rock units, originated/caused by brittle deformation due to faulting/shearing at both sides. It has modified by erosion/weathering and accumulated as ABGM at foothills, forming active slides, along both side slopes.

3.2.1.1.2 Rounded Boulder Gravels with Sand and Appreciable Amount of Fines (RBGM)

River bed is mainly occupied by RBGM material. Some exposure is also present at power house site near old Chinese Camp and Helipad Area. Due to formation of lake, the bed of the River is mostly covered with silt and sand extends up to Shishkat Bridge.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.2.1.1.3 Terrace Deposits

Terrace Deposits consist mainly of mixture of clay, silt, sand and gravels with occasional boulders. These are mostly developed in loose material (RBGM, ABGM, Morainic and Breccia) **(DWG No: AFS-GE-302,305 & 309)** in all villages, depending upon the availability of water. Most of the irrigation water channels are coming from glaciers. In Central Hunza (Hyderabad, Aliabad and Karimabad) water coming from Ultar and Hassanabad Glaciers. Similarly, from Gulmit and Passu Glacier. The Terrace Deposits are excavated to fulfil requirement for irrigation water from the melting of these glaciers.

3.2.1.1.4 Morainic Deposits

It consists mainly of material ranging in size from large boulders to clay size particles, angular to sub-angular, elongated and have flat surface **(DWG No: AFS-GE-299 & 302).** The direction of elongation indicates the route of advancement of glacier. These are well exposed throughout the valley.

3.2.1.2 Rock Units

The main rock units exposed in Project Area explored during Neo-tectonic Studies are as follows:

- Granitic gneiss
- Granodiorite
- Passu Slates
- Marbles

It is 70 to 120 km wide and 1400 km long structural zone comprises the Karakorum crustal plate which is one of the fragment of Cimmerian Collage derived from Gondwanaland and accerated to Eurasia. The stratigraphic history of the Karakorum is similar as that of Himalaya up to Cretaceous. The Project Site mostly present in the KAB consist of igneous and metamorphic rocks.

The brief description of the rock units is given below;

3.2.1.2.1 Granitic Gneiss

It is light grey to grey in color on fresh surface and weathers to light brown, coarse to very coarse grained, moderately to highly jointed, highly sheared up to higher elevation due to faulting, sparsely to moderately weathered, moderately hard to hard. It has well developed foliation with trending value N61ºW and plunging value 79ºNE. It is exposed at the right as well as at the left bank of the Hunza River. Some shear zones are also present within the unit **(DWG No: AFS-GE-293 to 312).**

On the basis of petrographic analysis, it is evident that the major constituents' minerals present in Granitic Gneiss are Quartz, oligoclase, biotite while amphibole, chlorite, muscovite, epidote, and tourmaline are present as minor constituent minerals. The high percentage of quartz grains show strong strain extinction, indicating that this unit has Alkali Silica Reaction (ASR) potential.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The rock may therefore not be used as a coarse aggregate with Ordinary Portland Cement (OPC) or High Alkali Cement. It may be used with low alkali cement, fly ash, pozzolan. Some chemical additives like lithium nitrate or silica fume can also be used to control this reaction. The Schmidt Hammer values ranges from **35** to **45 MPa** indicating that rock is moderately strong to very strong. But in some shear zone where rock is tectonized locally; this value reduces upto **18-22 MPa**.

3.2.1.2.2 Granodiorite

It is dark grey to blackish grey in color, weathers to brownish grey, medium to coarse grained, moderately weathered, moderately hard to hard, moderately jointed intruded by pegmatite and granitic gneiss. It is foliated with trend and plunge values of N60ºW/79ºNE. Further downstream it becomes light grey to grey in color, coarse to very coarse grained. It is crushed, mylonized, and sheared at places. It is well exposed at both banks where it is intruded by many pegmatite dykes. Some shear zones are also present in this unit.

On the basis of petrographic analysis, it is evident that granodiorite is quite dominate in the Project Area. The major constituents' minerals present in this unit are plagioclase, quartz, biotite, and amphibole while Iron, muscovite, chlorite, and epidote are minor constituents. The high percentage of Quartz grains show strong strain extinction, indicating that this unit has Alkali Silica Reaction (ASR) potential. The rock may therefore not be used as an aggregate with Ordinary Portland Cement (OPC) or High Alkali Cement or it may be used with low alkali cement, slag, fly ash, pozzolana. Some chemical additives like lithium nitrate or silica fume can also be used to control this reaction.

3.3 GEOLOGICAL STRUCTURES

The Project Area tectonically lies in KB . These units have undergone Karakorum as well as Himalayan Orogeny. The whole area has undergone/modified by two major fault systems MKT and Karakorum Strike Slip Fault (KSSF). The MKT system which accommodated southward thrusting. Karakorum Fault 800 km long dextral strike-slip fault that bounds western Tibet, extending from the Pamirs to Gar Basin. As the Project Area has undergone multiple episodes of tectonics events, many regional as well as local faults and their splays have formed as discussed below.

3.3.1 Faults

Many thrust fault system related to regional faults are present in the Project Area. There are many faults present in the vicinity of proposed ALHPP **(DWG No: AFS-GE-293 to 312).** These faults are splays of MKT and KSSF, and lies in between these two fault systems. These include:

- Batura Glacier- Hussaini Fault
- Borith Lake-Shamshal Nullah Fault
- Shishkat- Gulkin Glacier Fault
- Attabad -Hispar Valley Fault
- Central Hunza/Nagar- Chalt Fault

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Hassanabad Nullah Fault
- Hunza River-Nagar Fault

All these faults have been marked on the GT sheets and presented as **(DWG No: AFS-GE-318 to 320)**. The dip and strike values of major faults have been plotted on the drawings.

Some of these faults have been observed during Surface Geological mapping and marked on geological maps **(DWG No: AFS-GE-293 to 312).** The brief description of these units are: -

3.3.1.1 Attabad-Hispar Valley Fault :

It is thrust fault striking N30°E and dipping 40°SE, and is well exposed at the left side slope near the Project Area **(DWG No: AFS-GE-293 to 312).** This fault crosses the Hunza River and forming a junction point with Hunza River and Attabad Fault in Attabad village. The whole rock mostly granitic gneiss along its alignment is sheared / brecciated, forming fault breccia at many places. Due to high degree of shearing, many active slides have been originated along the whole slope. Rolling down of large boulder is quite common, and can be seen on old KKH. The retaining wall along this slide is fractured/jointed into parts due to operational stresses and downslope load movement. The ABGM along the slope is folded. It is clear indication that this fault has some movement, and is seismically active.

3.3.1.2 Attabad Fault:

This Thrust Fault is striking N60°W and dipping 52°NE, exposed in area rear of Attabad village. It is small scale fault and terminates along junction point of three faults. A large brecciated and sheared rock is present along this Thrust Fault. At the junction point of these faults **(DWG No: AFS-GE-293 to 312)** a large slide originated and destroyed about 2 Km of KKH. Sheared and brecciated rock can be seen on outcrop at right side slope up to higher elevation.

3.3.1.3 Attabad River Fault:

The exposure of this fault is present at right side slope of Hunza River. The breccia is well exposed at right side, just downstream of Sarat Suspension Bridge. The intensity of brecciation increases towards Salamanabad village. In fact, Salamanabad village is established on this breccia. It may be present up to higher elevation **(DWG No: AFS-GE-293 to 312).**

4 GEOLOGICAL & GEOTECHNICAL INVESTIGATIONS

4.1 SURFACE INVESTIGATIONS

The surface investigations / observations are one of the most important tools to reveal the geological conditions prevailing at the site. The natural processes operating on surface left clues to reveal the environments persisting in ancient time. Surface geological mapping is one of the best tool to check the geological conditions existing at site and to explore the deformation for the assessment of rock condition during the Feasibility Study.

4.1.1 Surface Geological Mapping

The Surface geological mapping of the Project Area has been carried out on 16 topographic sheets prepared by Survey Division Peshawar, HPO, WAPDA on scale 1:1000 with contour interval of 2 m, with the help of Total Station, Plane Table and Brunton compass and presented at scale of 1:2000 **(DWG No: AFS-GE-293 to 312).**The contacts between different rock units e,g granitic gneiss and granodiorite as well as between different soil units have been marked. Structural features like joint sets, faults, foliation and shear zones along with dip and strike values have been marked on these sheets.

Four geological cross sections were prepared along different alignments including, weir site, power tunnel intake area, penstock alignment & powerhouse area.

Photo 4-1 Surface Geological Mapping

4.1.2 Neo-tectonics Study

During the study of ALHPP, HPO, WAPDA, has identified the importance of Neo-tectonic studies, of this area being affected by Attabad slide in 2010. It is very important for the development of hydropower project in this area to develop the understanding of the Neo-tectonic setting operating under regional tectonic forces for the stability and planning of the hydropower project. All the geotechnical data procured during geotechnical investigations were

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

utilized for foundation evaluation of weir, sediment flushing channel/ undersluices and power house.

The area under study has covered by the 2 GT sheets 42 L/15 and 42 L/11 at scale of 1:50,000, covering 40 km upstream and 50 km downstream of slided mass. These GT sheets were enlarged and printed at a scale of 1:15000 and presented at scale of 1:40,000, and used in field for alignment of local as well as regional faults **(DWG No: AFS-GE-318 to 320).**.

4.2 SUBSURFACE INVESTIGATIONS

Sub-surface geological and geotechnical investigation program was prepared to probe the sub-surface foundation conditions at weir, sediment flushing channel/ under sluices and power house including borehole drilling and test pits excavation. Drilling of exploratory bore holes was executed by Drilling Division, Hydroplaning, and supervised by Directorate of Geology, Hydro Planning WAPDA, Lahore.

4.2.1 Drilling

The main objective of drilling was to determine the nature and engineering characteristics of soil and rock units at weir sediment flushing channel/ undersluices and power house. It was performed to observe the subsurface geological conditions at depth in order to find out nature of the different strata in subsurface, to estimate the behavior and nature of overburden material, the depth of water table encountered. The bearing capacity of the soil, “N” values were obtained by performing Standard Penetration Test (SPT) in soil, determine depth to bed rock. To assess the f conductivity, insitu permeability test in overburden and water pressure test (Lugeon) in rock have been carried out.

A total 06 bore holes with total drilling of 401m have been drilled for subsurface exploration at different structures. **(DWG No: AFS-GE-316).** The coordinates, structure, and depths of borehole are given in **Table 4.1 & 4.2**

Table 4-1 Co-ordinates of Boreholes

Sr. No	Borehole	Northing	Easting	Elevation (masl)
1	BH-1	4018100.45	484075.46	2415.79
2	BH-2	4017996.26	484089.59	2452.81
3	BH-3	4018061.58	483541.73	2456.92
4	BH-4	4017721.34	482609.57	2445.37
5	BH-5	4017906.94	481690.72	2318.04
6	BH-6	4017906.55	481605.02	2313.84

Table 4-2 Location of Boreholes

Sr. No.	Borehole	Depth (m)	Location
1	BH-1	90	Weir Site (Left abutment)
2	BH-2	60	Sediment Flushing Channel
3	BH-3	61	Sediment Flushing Channel
4	BH-4	80	Power Tunnel Alignment
5	BH-5	50	Power House Area
6	BH-6	60	Power House Area

Photo 4-2 Drilling Rig at BH-02 Sediment Flushing Channel .

For foundation evaluation of different structures, bore holes of varying depths have been drilled accordingly to estimated geological conditions prevailing in subsurface. Permeability tests have been performed using constant head method in overburden material at 3 m interval whereas water pressure tests (Lugeon tests) in bed rock have been performed at interval of 5 m or at change of strata. Rock cores and soil samples have been collected from all the bore holes at various depths for lab testing. All the tests have been conducted at CMTL, WAPDA Lahore. The logs of bore holes at different structures have been prepared. Permeability values in overburden material and lugeon values in rock have been calculated.

4.2.1.1 Standard Penetration Tests (SPT)

SPT has been carried out in boreholes in overburden which mainly consists of silty sand with clay intercalations. Split spoon samplers have been used to collect the samples. The material encountered in SPT sampler mainly consists of clayey silt. SPT relied upon to provide information about the properties of soils / weak rocks. The principal use of the SPT is to examine, i.e., subsurface investigation profile, soil classification, the determination of geotechnical design parameters estimating liquefaction potential of soils. In foundation designs, SPT in overburden material, blow counts (N Values) are typically used to estimate nature and

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

strength properties of soils used to calculate the bearing capacity for foundation. The results are presented in bore hole logs **Volume 4A**.

4.2.1.2 Cone Penetration Test (CPT)

CPT have been carried out in boreholes in gravelly Silty Sand with Clay intercalations. CPT relied upon to provide information about the properties of soils / weak rocks. The principal use of the CPT is to examine geotechnical design parameters, estimating liquefaction potential of soils. In foundation designs, CPT blow counts are typically used to estimate nature and strength properties of soils, used to calculate the bearing capacity for foundation evaluation.

4.2.2 Test Pits

A total of 10.test pits (3 m×3 m ×3 m) have been excavated in overburden material at weir site, slope along sediment flushing channel and power house area. Composite samples by cone and quarter method have been collected from each test pit. Different tests have been conducted on these samples to estimate the engineering properties of material.

To identify and proven source for coarse as well as fine aggregate, 4 test pits have been excavated. Samples collected from these pits were sent to CMTL, WAPDA, Lahore for testing to check their suitability for fine as well as coarse aggregate. The logs of test pits have been prepared and presented in **Volume 4A.**

4.2.3 Laboratory Testing

To investigate the engineering properties of rock and overburden material different rock cores and soil samples at weir, sediment flushing channel / under sluices and power house site have been sent to CMTL Lahore.

A total of 10 rock core samples from BH-04 (Power tunnel alignment)have been selected for evaluation of geotechnical engineering parameters for design purpose **(Table 4.3)**. The table below shows the testing program proposed in BH-04 at different depths.

A total of 15 samples, i.e. 3 block sample, 3 samples from borrow area, and 9 test pit samples have been selected for investigations. Samples from all tests pits have been selected by cone and quarter method and different test given in **(Table 4.4),** have been proposed to check their engineering properties and confirm their suitability as aggregate material.

All the laboratory tests on rock core samples have been conducted in CMTL WAPDA, Lahore. The detailed results are presented in laboratory testing **Volume 4B.**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5 EVALUATION OF LABORATORY TESTS

5.1 PETROGRAPHIC ANALYSIS

A total of 06 petrographic analyses have carried out to confirm the mineral assemblage in the particular rock unit. Another important feature of petrographic analysis is to determine Alkali Silica Reaction (ASR) by estimating the percentage of deleterious mineral especially quartz grains showing strong extinction to check it suitability in concrete mix design with Ordinary Portland Cement (OPC). For this purpose, 2 samples have been collected through excavation of test pits, 2 samples from different locations have been collected during surface geological mapping, and 01 drilling core sample has been collected from power tunnel alignment. The mineral assemblage more than 5% is considered as major mineral while other with less than 5% is consider as minor minerals. The detail is given in table below: -

Table 5-1 Petrographic Analysis Results

Sr. No.	Borehole No.	Rock Name	Major Minerals					Minor Minerals					Remarks / Description
			Quartz	K-Feldspar	Oligoclase	Biotite	Amphibole	Magnetite	Chlorite	Epidote	Muscovite	Carbonate	
1	Rock Samples	Foliated Granite	24	18	17	21	1	2	2	6	7	1	ASR Potential exists
2		Granite	32	26	14	6	3	2	4	1	3	3	ASR Potential exists
3		Granodiorite	24	11	20	15	16	2	3	5	2	2	ASR Potential exists
4		Granodiorite	26	12	25	14	11	2	3	3	2	2	ASR Potential exists
5	BH-04	Granitic Gneiss	30	13	28	17	4	1	3	1	2	1	ASR Potential exists

The petrographic analysis shows that granodiorite and granitic gneiss are the major rock units exposed at the Project Site. Quartz, plagioclase, K-feldspar, amphibole and biotite are the major mineral constituents. Both rocks units show strong quartz grains extinction and are deleterious in nature. Due to this reason, these rock units cannot be used with ordinary portland cement (OPC) as coarse aggregate. It can be used with low alkali cement, slag cement or cement with additives like fly-ash, pozzoloan, and chemical additives like lithium nitrate or silica fume.

Rock samples (Marble) from Passu village area along KKH have been collected and sent to laboratory to conduct petrographic analysis. Result shows that, marble consists of 91.5% calcite, 5% dolomite, with quartz, magnetite and muscovite as minor minerals. The rock has no alkali carbonate nor alkali silica and therefore can be used as coarse aggregate with OPC.

5.2 DIRECT SHEAR TEST

One sample from BH-04 has been selected for Direct Shear Tests from depth of 56 to 56.35m. Both normal and shear stress have been applied gradually to observe the strain and displacement rate, under applied stress. The result shows that cohesion “C” has 0.595 MPa with angle of shear resistance “ϕ” is 21.8 deg.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The direct shear test results show that both values are in safe limit, indicating that rock is moderately strong to strong.

5.3 ROCK CORE MODULUS

02 core samples from BH-04 and 3 bulk samples from borrow area have been selected to carry out the Rock Core Modulus including Young's Modulus, and Modulus of Deformation, for which the mode of failure has also been observed and presented in table 5-2

Table 5-2 Rock Core Modulus Test Results

Sr. No.	Bore Hole	Location	Depth (m)		Test Results (MPa)		
			From	To	Young's Modulus	Modulus of Deformation	Mode of Failure
1	BH-04	Power Tunnel Alignment	48.0	48.25	$2.29*10^4$	$1.15*10^4$	Axial
2			61.0	61.30	$1.83*10^4$	$9.16*10^3$	Axial
3	Bulk Samples	Passu Area	-	-	$7.52*10^4$	$3.76*10^4$	Diagonal & Axial
4		Powerhouse Area	-	-	$4.16*10^4$	$2.08*10^4$	Diagonal & Axial
5		Slided Mass	-	-	$4.96*10^4$	$1.88*10^4$	Diagonal

Rock samples from BH-04 show "Axial" mode of failure while bulk samples for borrow area of coarse aggregate shows "Diagonal & Axial" mode of failure exists with relative low Poisson's Ratio. The values of Young's Modulus indicate that all the rocks encountered are moderately hard to hard. Result of borrow area shows that the Passu Area rock (Marble) show very high value with diagonal as well as axial mode of failure, this shows that marble is hardest among all samples for borrow area.

5.4 POINT LOAD STRENGTH INDEX (PLSI) TEST

A total of 7 samples, 3 from BH-4 and 4 from borrow area have been selected to carry out (PLSI) Test. The main purpose of the (PLSI) Test is to determine/calculate the strength index of rock mass. For this purpose, ASTM standard D 5731-95 has been used to carry out the (PLSI) Test. The values of these tests are given in table below: -

Table 5-3 Point Load Strength Index Test Results

Sr. No.	Bore Hole No.	Location	Depth (m)		Test Results		
			From	To	Is (Mpa)	Is 50 (Mpa)	Failure
1	BH-04	Power Tunnel Alignment	21.00	21.15	4.04	3.93	Diametrically
2			31.21	31.52	5.39	5.23	Diametrically
3			43.25	43.55	3.14	3.05	Diametrically
4	Bulk Samples	TP-08	-	-	1.81	1.66	Diametrically
5		Passu Area	-	-	4.11	4.30	Diametrically
6		Powerhouse Area	-	-	3.97	4.15	Diametrically
7		Slided Mass	-	-	5.68	5.94	Diametrically

Point Load Index value is an index of strength but not a strength value. The above table shows that all the values except 1.66 MPa (TP-08) is relatively low while all others have reasonably good values which proves that rock strength is moderately high and durable.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5.5 UNIAXIAL COMPRESSIVE STRENGTH (UCS) TEST

A total of 9 samples, 3 samples from BH-04, 3 samples from test pits, and 3 bulk samples from different borrow areas have been selected to carry out the (UCS) Test. The main purpose of the (UCS) Test is to determine the compressive strength under uniaxial load in an unconfined state. The strength is determined by using ASTM standard D-2938. The values are given in table below: -

Table 5-4 Uniaxial Compressive Strength Test Results

Sr. No.	Bore Hole / Test Pits	Location	Depth (m)		Test Results	
			From	To	UCS (MPa)	Failure Mode
1	BH-04	Power Tunnel Alignment	38.14	38.43	49.2	Diagonal
2			56.00	56.39	45.2	Diagonal
3			68.00	68.23	38.5	Diagonal
4	TP-7	Slided Mass (Left side)	-	-	52.40	Diagonal
5	TP-8	Slided Mass (Right side)	-	-	71.91	Diagonal
6	TP-9	Slided Mass (Right side)	-	-	34.63	Diagonal
7	-	Passu Area	-	-	47	Diagonal
8	-	P/H Area	-	-	88	Diagonal & Axial
9	-	Slided Mass	-	-	59	Diagonal & Axial

The rock strength given in table shows that the rock has medium strength and moderately hard.

5.6 INDIRECT TENSILE STRENGTH (ITS) TEST

(ITS) Test has been carried out on core sample collected from BH-04, at depth from 43.25 to 43.55m. A cylindrical specimen is loaded diametrically and tensile deformation perpendicular to the loading direction yields a tensile failure. ASTM standard D-3967 has been used to carry out the indirect tensile strength.

The (ITS) Test is mostly estimated as 10 to 15% of Uniaxial Compressive Strength (UCS). The lab test value is 6.46 MPa which indicates that rock is moderately hard.

5.7 HOEK TRIAXIAL COMPRESSIVE STRENGTH (HTCS) TEST

(HTCS)Test has been carried out on 2 rock core samples collected from different depths from BH-04. (HTCS) Test is used to determine the shear strength of rock samples. The test can determine that how applied stress is related to deformation experienced by rock samples as well as to determine the angle of internal friction and cohesion of the rock samples. ASTM standard D-2664 has been used to carry out the (HTCS) Test. The values are given in table below: -

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 5-5 Hoek Triaxial Compressive Strength Test Results

Sr. No.	Borehole No.	Depth		Cohesion "C" MPa	Angle (Ø) deg.
		From	To		
1	BH-04	52.60	53.00	2.18	27.749
2		63.00	63.35	0.60	15.543

The values of cohesion "C" and angle of internal friction "**Ø**" calculated by (HTCS)Test, given in table indicates that the shear strength of the rock core samples is low to moderate.

5.8 PROPERTY INDEX

A total of 6 rock core samples from BH-04 at different depths have been sent to CMTL, Lahore. Property index tests were conducted under ISRM standard to determine the properties of rock. The table below shows results of test on rock core samples

Table 5-6 Property Index Test (Core) Results

Sr No.	Sample	Depth		NMC (%)	Sp. Gravity	Porosity	Dry Density	Water Abs. (%)
		From	To					
1	BH-04	38.14	38.43	0.12	2.73	1.58	2.69	0.59
2		43.25	43.55	0.21	2.76	1.17	2.72	0.43
3		52.60	53.00	0.04	2.77	0.69	2.75	0.25
4		56.00	56.39	0.27	2.77	1.25	2.73	0.46
5		63.00	63.35	0.07	2.76	0.81	2.73	0.30
6		68.00	68.23	0.09	2.77	0.72	2.75	0.26

Table 5-7 Property Index Test (Test Pits) Results

Sr No.	Sample	Material	Sp. Gravity	Org. Impurities	Water Abs. (%)
1	TP-1	Fine	2.68	NIL	1.11
2	TP-2	Coarse	2.71	-	-
3		Fine	2.65	NIL	1.20
4	TP-3	Fine	2.17	NIL	-
5	TP-4	Fine (0.0-1.5m)	2.30	NIL	-
6		Fine (1.5-3.0m)	2.27	-	-
7	TP-5	Fine	2.36	NIL	-
8	TP-6	Coarse	2.67	-	-
9		Fine	2.70	-	1.04
10	TP-8	Coarse	2.72	-	-
11		Fine	2.69	-	1.12
12	Block (TP-3)	Fine	2.36	-	-
13	Block A (TP-10)	Fine	2.38	-	-
14	Block B (TP-10)	Fine	2.30	-	-
15	Passu	Coarse	2.84	-	0.37
16	P/H Area	Coarse	2.78	-	0.27
17	Slided mass	Coarse	2.75	-	0.33

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The values given in table 5.7 (A&B) shows that all the values of fine and coarse aggregate fall in permissible limits besides water absorption test which shows some relative higher values with no organic impurities.

5.9 LOS ANGELES ABRASION (LAA) TEST

A total of 4 samples, from test pits, of different borrow areas have been selected to carry out the (LAA) Test. The main purpose of this test is to indicate aggregate toughness and abrasion characteristics. Aggregate abrasion characteristics are important because the constituent coarse aggregate must resist crushing, degradation and disintegration. ASTM standard C-131 is used to perform this test for 500 revolutions. The values are given in table below

Table 5-8 Los Angeles Abrasion Test Results

Sr. No.	Test Pits	Location	Test Results	
			Percentage (%) Wear	Uniformity of wear
1	TP-7	Slided Mass (Left side)	48	0.41
2	-	Passu Area (marble)	27	0.20
3	-	Power House Area	18	0.21
4	-	Slided Mass	56	0.34

(LAA) Test results indicate that, samples of Passu Area (marble) and powerhouse area show minimum wearing ability and values ranges within the permissible limits while TP-7 and samples from slided mass show high percentage of wearing.

5.10 SULPHATE SOUNDNESS TEST

A total of 03 samples, from different borrow areas have been selected to carry out the Sulphate Soundness Test. The main purpose of this test is to determine the aggregate resistance to change of volume due to change of physical condition and weathering. These physical conditions include freezing and thawing, temperature change, alternative change of drying and wetting in normal condition and alternative change of drying and wetting in salt water for 5 No. of cycles. ASTM standard C-88 is used to perform this test. The values are given in table below: -

Table 5-9 Sulphate Soundness Test Results

Sr. No.	Location	Test Results		
		% Passing Designated Sieve after Test	Weighted Percent Loss	Total
1	Passu Area	0.96	0.89	0.89
2	Power house	0.85	0.81	0.81
3	Slided Mass	1.88 & 1.78	1.69 & 0.18	1.87

Sulphate Soundness Test results indicates that, samples of Passu Area (marble) and powerhouse area show minimum loss while slided mass material shows relatively double values. Therefore, both can be used as an aggregate with concrete.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5.11 CRUSHING VALUE OF AGGREGATE

A total of 5 samples, 2 samples from test pits and 3 samples from different borrow areas have been selected to carry out crushing value of aggregate. The main purpose of this test is to determine the aggregate resistance to wear and tear. BS-812 (1990) Part 110 is used for performing this test with fraction used (3/4"-1/2"). The values are given in table below: -

Table 5-10 Crushing Value of Aggregate Test Results

Sr. No	Location	Depth	Crushing Value
1	TP-6	0.0-3.0	43
2	TP-8	0.0-3.0	NP
3	Passu Area	-	24
4	Powerhouse Area	-	27
5	Slided Mass	-	22

Table 5-10 shows that, samples of Passu area (marble), powerhouse area and slided mass fall in permissible limits while TP-6 shows relatively high value.

5.12 FLAKINESS/ELONGATION INDEX

A total of 5 samples, 2 samples from test pits and 3 samples from different borrow areas have been selected to carry out the particle shape of the aggregate specimen and each particle shape being preferred under specific condition. For cement concrete types and base coarse construction and bituminous-construction, the presentence of flaky and elongated aggregate particles are considered undesirable as they may cause inherent weakness with possibility of breaking down under heavy loads. BS-812 Part 105.1 & 105.2 is used for performing this test. The values are given in table below: -

Table 5-11 Flakiness/Elongation Index Test Results

Sr. No.	Location	Depth	Flakiness Index
1	TP-8	0.0-3.0	13
2	TP-9	0.0-3.0	04
3	Passu Area	-	22
4	Powerhouse Area	-	23
5	Slided Mass	-	21

Table 5-11 shows that, all samples fall in permissible limits.

5.13 CONSOLIDATION TEST

A total of 3 samples undisturbed box samples, from different test pits have been selected to carry out consolidation tests. The main purpose of this test is to determine the magnitude and rate of consolidation of soil when it is restrained laterally and drained axially while subjected to incremental applied controlled stress loading. ASTM Standard D-2435 is used to perform this test. The values are given in table below: -

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 5-12 Consolidation Test Results

Sr. No	Block Sample	Moisture Contents		Bulk Density mg/cm		Dry Density mg/cm		Void Ratio "e"		Saturation (%)	
		Initial	Final	Initial	Final	Initial	Final	Initial	Final	Initial	Final
1	TP-10 (A)	9.8	27.0	1.66	1.97	1.51	1.55	0.775	0.725	33.8	99.8
2	TP-10 (B)	4.2	29.0	1.52	1.94	1.46	1.51	0.837	0.778	13.4	99.8
3	TP-3	6.9	27.7	1.54	1.96	1.44	1.54	0.866	0.744	21.5	99.7

Consolidation plays an important role in stability analysis for the embankment, footings or a column constructed on clayey soils. The settlement behavior of these structures and the pore pressure needs to be investigated for construction on these soils. Table 5-12 shows that, the clayey silt fall in permissible limits and therefore may be considered as impervious blanketing material.

5.14 SWELLING POTENTIAL, UNIT WEIGHT AND NMC

A total of 7 soil (clayey silt) samples, i.e. 3 undisturbed block samples, 4 disturbed samples from different test pits have been selected to investigate swelling potential of soil. The main purpose of this test is to determine the swelling potential when come in contact with water. The values are given in table below: -

Table 5-13 Swell Potential, Unit Weight and NMC

Sr. No	Location	Depth	Swell Potential (KPa)	Unit Weight mg/m^3	NMC (%)
1	TP-2	2.0-3.0	39.5	-	-
2	TP-3	0.0-3.0	30.0	-	-
3	TP-4	1.5-3.0	12.5	-	-
4	TP-5	1.5-3.0	31.5	-	-
5	Block (TP-3)	1.0	22.5	1.683	3.88
6	Block (TP-10) A	0.5	23.0	1.688	3.72
7	Block (TP-10) B	1.5	25.0	1.691	3.18

All the samples of clayey silt show high swelling potential irrespective of TP-4, having moderate swelling potential and needs proper attention prior to their use as fine aggregate or for the foundation while unit weight and NMC fall in permissible limits.

5.15 MODIFIED PROCTOR TEST

A total of 5 of samples, from different test pits of borrow areas have been selected to carry out Modified Proctor test. The main purpose of this test is to determine the maximum compaction at corresponding moisture content of different types of soil and the relationship between dry density and moisture content. ASTM standard D-1557 is used to carry out this test. The values are given in table below:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 5-14 Modified Proctor Test Results

Sr. No	Location	Depth	Max. Dry Density (mg/m^3)	O.M.C (%)
1	TP-2	2.0-3.0	1.893	13.30
2	TP-3	0.0-3.0	1.887	13.05
3	TP-4	0.0-1.5	1.783	10.54
4	Block TP-3	1.0	1.881	12.87
5	Block TP-10	0.5	1.878	12.80

Table 5-14 shows that, all the values fall in permissible limits.

5.16 ACCELERATED MORTAR BAR TEST

A total of 5 samples; 2 samples from test pits and 3 bulk samples from different borrow areas have been selected to carry out Accelerated Mortar Bar Test. The main purpose of this test is to determine the changes in volume / expansion of material, either fine or coarse when mixed with ordinary Portland Cement (OPC) and reading for 28 days. ASTM Standard C-1260 is used to conduct this test. The values are given in table below: -

Table 5-15 Accelerated Mortar Bar Test Results

Sr. No	Location	Depth	Material	Average Change (28 days)	Average Expansion (28 days)
1	TP-1	0.0-1.3	Fine aggregate	0.099	0.039
2	TP-2	0.0-2.0	Fine aggregate	0.106	0.042
3	Passu Area	-	Coarse aggregate	0.235	0.093
4	P/H Area	-	Coarse aggregate	0.251	0.099
5	Slided mass	-	Coarse aggregate	0.246	0.097

All values of coarse as well as fine aggregate fall under permissible limits and can be used as concrete aggregate with OPC.

5.17 GRAIN SIZE ANALYSIS

A total of 15 of samples, from each test pits at different depth have been selected to carry out Grain Size Analysis. The main purpose of this test is to determine the different grain sizes contained within a soil. The mechanical or sieve analysis is performed to determine the distribution of the coarser, larger-sized particles, and the hydrometer method is used to determine the distribution of the finer particles. ASTM standard D-422 is used to carry out this test. The values are given in table below:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 5-16 Grain Size Analysis Results

Sr. No.	Test Pit	Depth (m)	Boulder %	Gravel %	Cobbles %	Sand %	Passing # 200	Silt %	Clay %
1	TP-1	0.0-1.3		0		99	1		
2	TP-2	0.0-2.0		0		76	24		
3		2.0-3.0		0		0		55	45
4	TP-3	0.0-3.0		0		0		58	42
5	TP-4	0.0-1.5		0		51		39	10
6		1.5-3.0		0		24		66	10

15	Block (B) TP-10	1.5		0		0		56	44

5.18 ATTERBERG LIMITS

A total of 8 samples, from different depth of test pits have been selected to carry out Atterberg Limits. The main purpose of this test is to determine the critical water contents of a fine-grained soil, its shrinkage limit, plastic limit, and liquid limit. The Atterberg limits can be used to determine the response of soil to change in moisture content exhibiting the consistency from hard and soft to rigid and pliable, termed as plasticity. ASTM standard D-422 is used to carry out this test. The values are given in table below: -

Table 5-17 Atterberg Limits Results

Sr. No.	Test Pit No.	Depth (m)	L.L %	P.L %	P.I %	Shrinkage. Limit %
1	TP-2	2.0-3.0	43	31	12	25.2
2	TP-3	0.0-3.0	40	29	11	23.8
3	TP-4	0.0-1.5	NP	-	-	-

6 GEOLOGY AND FOUNDATION EVALUATION

6.1 GENERAL

The rocks exposed in Project Area consists of granodiorite and granitic gneiss (ganitoide) intruded by pegmatite dykes belong to Karakorum Batholith. Most of the structures i.e. weir with overtopping spillway, sediment flushing channel, pedestals of penstock and powerhouse lie on overburden material. About 2.1 km long power tunnel is proposed at left side and will be excavated through granodiorite and granitic gneiss.

On the basis of surface geological mapping, geological x-sections, borehole logs, test pits excavation and laboratory test results, the foundation evaluation of various engineering structures proposed for Attabad Lake Hydropower Project (ALHP) have been made and describe in the following sections: -

6.2 WEIR SITE

6.2.1 Surface Geological Mapping

The surface geological mapping of the main weir area has been carried out at a scale of 1:1000 with the help of Total Station, Plane Table and Brunton Compass and presented at 1:2000 scale. A geological X-section along line AA` has been developed and presented as drawing **(DWG No: AFS-GE-313).** The main purpose to develop geological x-section is to estimate condition prevailing in subsurface i.e. overburden thickness, extension / alignment of faults, extension / trend of rock units in the subsurface.

Photo 6-1 A View of Weir Site.

An overtopping concrete weir founded on slided mass is proposed after foundation treatment. Geological rock units with which weir has to be abut, includes granodiorite, intruded by pegmatite veins at right side. On left side, weir has to be abut with ABGM formed by slided mass **(DWG No: AFS-GE-297 & 298).** Some treatment / engineering solution have to be implemented for stability of the weir **(Photo 6-1)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6.2.2 Boreholes Drilling at Weir Site

A borehole BH-01, has been drilled at left side slope to investigate the subsurface geological conditions. The location of the boreholes is presented on drawing **(DWG No: AFS-GE-316).** No rock has been encountered in this borehole up to 90 m. The core recovery CR (%) and permeability test results are given in **Table 6-1**, and graphically presented in **Figure 6-1**. The permeability tests were conducted after every 3 m. In most of tests, head could not be maintained due to cavities/ open works encountered in subsurface. The borehole has been stabilized with cement.

Table 6-1 Summary of BH-01 (Weir Site Left Abutment)

PERMEABILITY TEST IN OVERBURDEN	
K (cm/sec) $<10^{-6}$	Impervious
K (cm/sec) 10^{-6} to 10^{-4}	Semi-pervious
K (cm/sec) $>10^{-4}$	Pervious

PERMEABILITY TEST (Lugeon) IN ROCK	
0 to 5	Low Permeable
5 to 15	Slightly Permeable
15 to 25	Permeable
>25	High Permeable

On the basis of drilling borehole log, a graph is developed between CR (%) Vs Depth (m), and is presented as **Figure 6-1.**

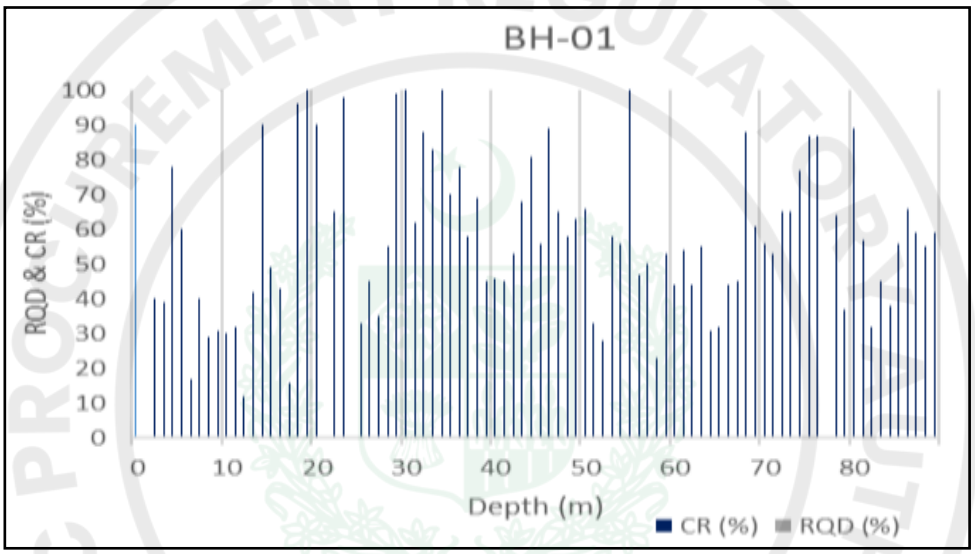

Figure 6-1 Graphical Representation of CR Vs Depth of BH-01.

It is noticed that head could not be maintained throughout the drilling of borehole. 100 % water loss has been observed. It indicates that slide mass is highly permeable with large cavities and open works which required cementing for stabilization of bore holes during drilling.

6.3 INTAKE AREA

The surface geological mapping of the intake area has been carried out at a scale of 1:1000. and presented at 1:2000 scale. A geological X-section along line BB` has been developed and presented as drawing **(DWG No: AFS-GE-313).** The main purpose to develop geological x-section is to estimate condition prevailing in subsurface i.e. overburden thickness, extension/alignment of faults, extension/trend of rock units in the subsurface.

The intake area is proposed at the left side of the Hunza River. Granodiorite rock is exposed at steep angle where it is hard, massive, strong to moderately strong with Schmidt hammer values ranges from 40 to 58 MPa **(DWG No: AFS-GE-295 & 298).** The rock is foliated where platy minerals are aligned in specific orientation with trending at N42°W and plunging at 52°NE. Different joint sets measured at the outcrop is given below

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

N20°W/50°NE	**N62°E/64°NW**	**N24°W/49°SW**
N25°W/61°NE	**N85°W/82°SW**	**N06°E/88°SE**
N58°E/88°NW	**N85°W/67°NE**	**N75°E/74°SE**

Photo 6-2 Proposed Intake Area for Power Tunnel

Granodiorite rock is hard, strong to moderately strong, and sparsely to moderately jointed **(Photo 6-2)**. But at higher elevation, the rock is highly jointed and sheared, having vertical open joints which must be treated for stability and safety.

6.4 POWER TUNNEL

6.4.1 Surface Geological Mapping

The surface geological mapping of the power tunnel alignment has been carried out at a scale of 1:1000. and presented at 1:2000.

Photo 6-3 Rolling down of Scree along Active Slide

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

It is observed during surface geological mapping that a fault is running obliquely across the alignment of power tunnel alignment **(DWG No: AFS-GE-296,297,300,303,304 & 307).** A geological X-Section CC` has been developed to estimate the subsurface conditions and presented as **(DWG No: AFS-GE-303).** The power tunnel has to be excavated mostly through the granodiorite with subordinate granitic gneiss at the left side slope of Hunza River. The strength of rock reduces downstream and near the termination point of slided mass, brecciated/ gaugic rock is present/exposed **(DWG No: AFS-GE-303).** Rolling down of large boulders are quite common at this point **(Photo 6-3).** The rock units are quite crushed, sheared and brecciated forming active slides throughout its alignment.

A borehole BH-04 has been drilled to estimate the rock conditions in the subsurface. The brief description of CR and RQD is given in table 6-2 below.

Table 6-2 Summary of Borehole BH-04

Depth (m)		CR(%)	RQD(%)	Lugeon	Depth (m)		CR(%)	RQD(%)	Lugeon
From	To				From	To			
0	1				35	38	94	91	
1	2	14			38	40	97	94	2.60
2	3	12			40	43	98	98	
3	4	12			43	45	98	97	3.77

19	20	91	90	1.22	60	63	99	99	
20	23	97	89		63	65	99	99	
23	24	92	60		65	68	100	100	
24	25	98	98	1.45	68	70	100	100	
25	27	96	94		70	73	99	99	
27	30	96	91	1.68	73	75	100	100	
30	32.5	95	76		75	78	100	100	
32.5	35	96	83	0.64	78	80	100	100	

Lugeon test has been conducted in the field to check the permeability condition of the rock mass at every 5 m interval.

On the basis of data collected during borehole logging, a graph has been developed between depth Vs RQD and CR and presented as Figure 6.2.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

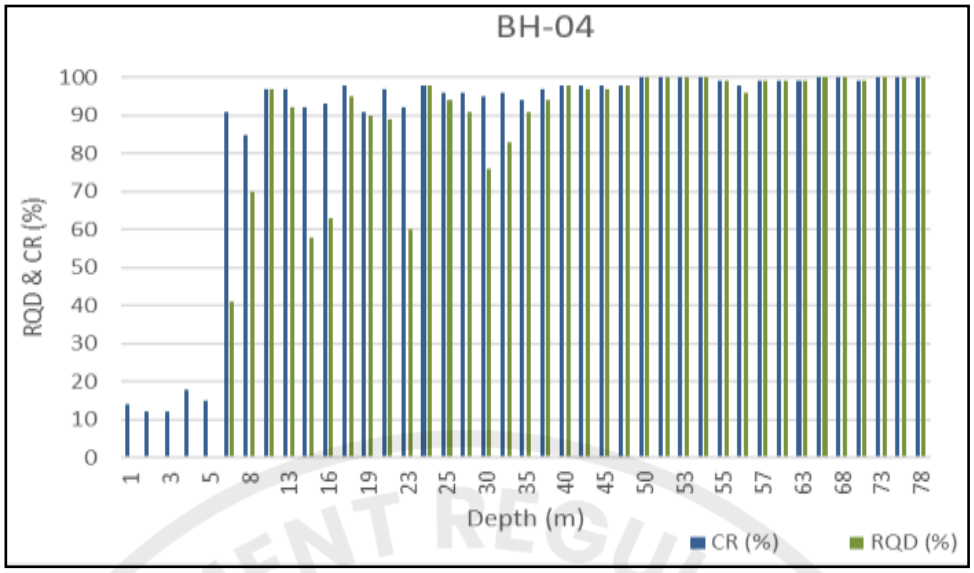

Figure 6-2 Graphical Representation of RQD&CR Vs. Depth of BH-04

During drilling works, it is estimated that the RQD values in upper 23 m is fair after that the value tends to excellent to good and good. The lugeon values calculated after every 5 m interval indicate that rock is low permeable. It shows that rock in sparsely jointed in subsurface. The lab test results indicate that in spite of the fact that RQD is quite high in lower portion but the strength index is moderate. The value of all tests indicate that the rock in BH-04 is moderately hard and moderately strong with low cohesion “C” and low angle of internal friction “Ø”. While excavating through this portion, some treatment is required to enhance for stability of structure.

6.5 SEDIMENT FLUSHING CHANNEL

6.5.1 Surface Geological Mapping

The surface geological mapping of the power tunnel alignment has been prepared at a scale of 1:1000 in field and presented at 1:2000 scale. It is proposed on the left side of Hunza River **(Photo 6.4)**. It is observed during surface geological mapping that the sediment flushing channel has to be excavated through ABGM of slided mass **(DWG No: AFS-GE-297 & 298).**.

Slided mass covers an area of about 1 km and consist of huge volume of ABGM. One of the difficult and critical task is to stabilize the both side slopes along the sediment flushing channel. The large boulders of more than 25 m in length are present in slided mass. Benching is one of the best solution for such type of slope to stabilize. At some place, mashing or gabion may be helpful for slope stabilization.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 6-4 Intake Area of Sediment Flushing Channel.

6.5.2 Borehole Drilling

To investigate the nature of material exposed at left side slope, two borehole BH-02 and BH-03 have been drilled at outlet and intake of sediment flushing channel respectively. The summary of these boreholes is given in table 6.3 and 6.4.

Table 6-3 Summary of Borehole BH-02

On the basis of data collected during borehole logging, a graph has been developed between depth Vs CR and presented as **Figure 6.3**. Permeability tests were performed at every 3 m interval. It is noticed that throughout the borehole drilling, head could not be maintained and 100% water loss is observed during drilling.

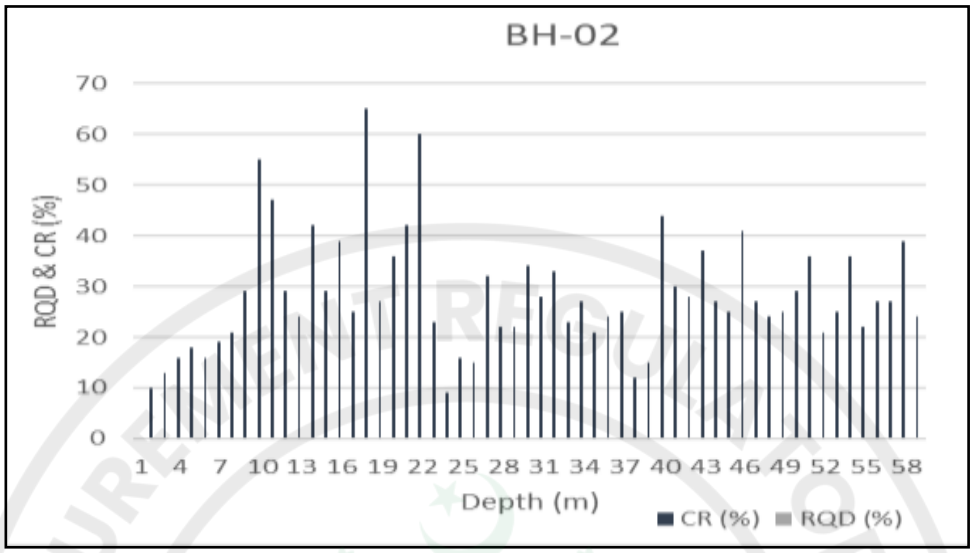

Figure 6-3 Graphical Representation of CR Vs Depth .

On the basis of data collected during borehole logging, a graph has been developed between depth Vs CR and presented as **Figure 6.4**.

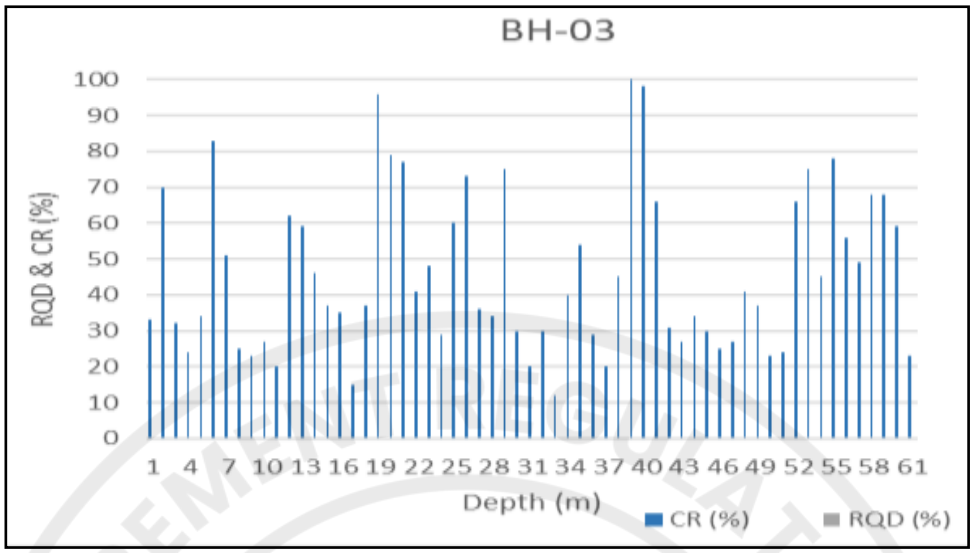

Figure 6-4 Graphical Representation of CR Vs Depth of BH-03.

Permeability tests have been performed at every 3 m interval. These values indicate that the material is pervious.

It is clear from the drilling logs that rock is not encountered upto 60 m in both boreholes. The drilling data and lab test results show that the boulders of overburden material (ABGM) are hard and moderatly strong. The slope can be stablized by benching. The permeability values in BH-02 are quite high as head cannot be maintained throughout drilling while in BH-03 the permeability values show that strata is pervious.

6.5.3 TEST PITS

Two test pits TP-5 and TP-6 have been excavated along sediment flushing channel at inlet and outlet area. In TP-5, it is observed that from 0-1.5 m, ABGM and RBGM is embedded into clayey silt while further from 3 m, fine to very fine grained, moist clayey silt is present. In TP-06 and 07, large boulders with subordinate fine material is present, which was originated from slided mass. During excavation of these test pits, large gaps have been found between these boulders.

6.6 SURGE TANK AND PENSTOCK ALIGNMENT

The surface geological mapping of the surge tank and penstock alignment have been carried out at a scale of 1:1000 in the field and presented at 1:2000 scale. It is proposed on the left side of Hunza River **(Photo 6-5)**. It is observed during surface geological mapping that the granodiorite rock with granitic gneiss is exposed in surge tank area. It is moderately hard, sheared and highly jointed **(DWG No: AFS-GE-307).**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 6-5 Proposed Area for Surge Tank.

From surge tank 450 m long penstock with diameter of 3.6 m is proposed up to powerhouse. Piers will support penstock alignment. The foundation of piers will be laid on overburden material **(DWG No: AFS-GE-306 & 309).** The presence of clayey silt may create problem and might be excavated prior to establish foundation for piers **(Photo 6-6)**.

Photo 6-6 Proposed Alignment of Penstock.

6.7 POWER HOUSE

The surface geological mapping of the power tunnel alignment has been carried out at a scale of 1:1000 in the field and presented at 1:2000 scale. It is proposed on the left side of Hunza River on a flat area **(Photo 6-7)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 6-7 Proposed Power House Area.

It is observed during surface geological mapping that thick clayey silt has been deposited having depth of about 30 m as confirmed by drilling (**BH-5 & BH-6**). It is interbedded in upper layers by RBGM while pure clayey silt found in depth. It is deposited due to choking of Hunza River when Salmanabad slide occurred **(DWG No: AFS-GE-309)..** A geological X-section DD` has been established to estimate the sub surface conditions and presented as **(DWG No: AFS-GE-315).**

6.7.1 Borehole Drilling

To explore the nature of foundation of power house material two boreholes, BH-05 and BH-06 with drilled depth of 50 m and 60 m respectively, have been drilled at powerhouse area. The summary of these boreholes is given in table 6-5 and 6-6 respectively.

Table 6-5 Summary of Borehole BH-05

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

On the basis of data collected during borehole logging, a graph has been developed between depth Vs CR and presented as **Figure 6-6**. Permeability tests were performed at every 3 m interval.

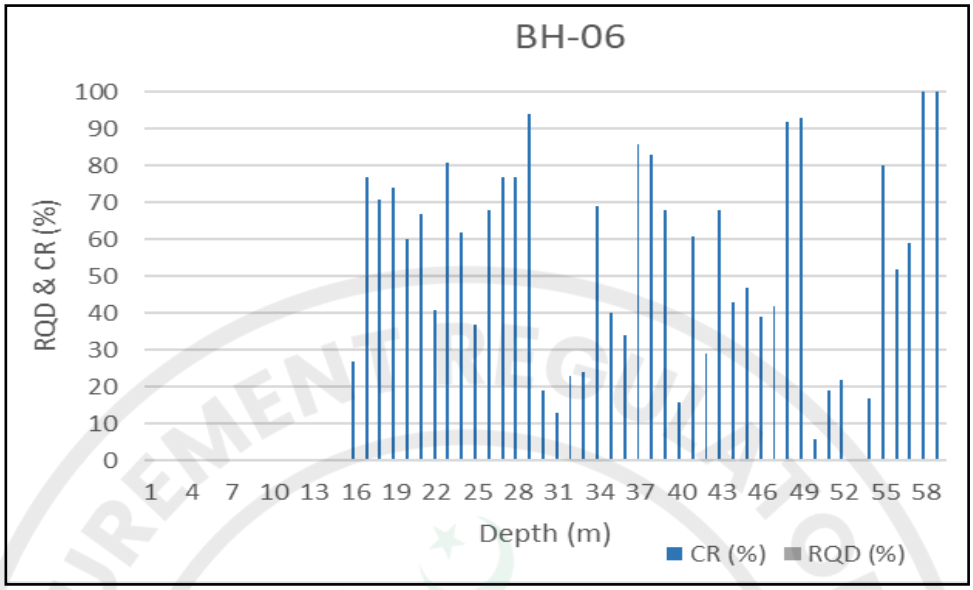

Figure 6-6 Graphical Representation of CR Vs Depth

It is clear from the drilling data that about 15 m clayey silt in BH-06 and about 30 m in BH-05 has been encountered during drilling. SPT has been conducted in the clayey silt for 18 inches penetration in these boreholes. It is estimated from this data that firm to stiff clayey silt is present. The permeability tests conducted in this strata show that they have relatively high hydraulic conductivity. The lab test results indicate that the clayey silt has swelling potential.

Foundation of the powerhouse will be lying on overburden material. The whole thickness of clayey silt layer has to be removed/excavated prior to establish the foundation of powerhouse.

6.8 TAILRACE CHANNEL

The surface geological mapping of tailrace channel has been carried out at a scale of 1:2000. It is proposed on the left side of Hunza River. It is observed during surface geological mapping that the whole channel has to be excavated through the overburden material **(DWG No: AFS-GE-309).**. Water after generating electricity will again join Hunza River near Sarat village suspension bridge.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

7 CONSTRUCTION MATERIAL

7.1 GENERAL

Construction material required for various structures of ALHPP is available in ample quantity within/near the Project Area in economic haulage.

The rocks granodiorite and granitic gneiss are exposed in/near the Project Area. Both are acidic rocks and cannot be used as coarse aggregate with Ordinary Portland Cement (OPC) due to alkali silica reaction (ASR). Both rocks show deleterious quartz more than 5%. More over 10 test pits have been excavated for the study of aggregate material and foundation condition. These have been excavated in river bed, slided mass and fine deposits near old Chinese camp in power house area. Samples of marble have been collected from Passu area to conduct laboratory testing in CMTL WAPDA, Lahore.

7.2 FINE AGGREGATE

Two types of fine aggregate sand and clayey silt have been selected for testing and proven source for fine aggregate. Samples have been collected from 0 to 3 m depth (by coning and quartering method) for laboratory testing and sent to CMTL, WAPDA, Lahore.

7.2.1 Sand Quarry

To fulfil the quantity of sand material during construction of ALHPP, ample quantity of this material is deposited in the tail area of Attabad Lake near Shishkat Bridge **(Photo 7-1)**. A test pit TP-1 has been excavated, and samples have been collected for lab testing. Log of test pit is given in **(Volume 4A)**. Gradation test, indicates that 99% sand with only 1% silt and clay is present **(Table 5-15 & 5-16)**. The results of Accelerated Mortar Bar indicate minimum average expansion (0.039) for 28 days. Specific gravity and water absorption values also fall in permissible limits. The results of lab testing are provided in **Volume 4B.**

Photo 7-1 Quarry Area Selected for Sand near Shishkat Bridge.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The lab. test results show that it can favorably be used as sand quarry site for construction of ALHPP.

7.2.2 Silt and Clay Quarry

For fine aggregate (Clayey silt) 3 test pits 3x3x3m have been excavated to analyze the nature of material present in river bed. Two test pits TP-2 & TP-3 in helipad/powerhouse area and TP-10 near Klin area, near Ganesh Bridge, have been excavated to explore the subsurface geological conditions prevailing in the area **(Photo 7-2)**. Both composite as well as block samples from each test pit have been collected for lab testing.

Photo 7-2 TP-3, Excavated for Clayey Silt in P/H Area.

Lab test results indicate that the material consists of clayey silt with clay index ranges from (40-45%). Atterberg Limits and Swell Potential show that some treatment may be needed prior to their use. Results of Modified Proctor test on block and composite samples indicate that max dry density 1.7 to 1.8 mg/m^3 for clayey silt can be attained in range of 10 to 13% optimum moisture contents (ch. 5, Table 5-14). The laboratory test results can be seen in **Volume 4B**.

Another huge source of borrow area for silt and clay is present at brick kiln area near Ganesh Bridge along KKH. It lies in economic haulage. A test pit TP-10 has been excavated in clayey silt and two block samples were collected from this pit and sent to CMTL to conduct different tests. The log of test pit is presented in volume 4A. The Lab test results have been collected and interpreted in chapter 5.

It indicates from lab test results that, clayey silt is present and can be used ase blanket material to minimize the seepage. The ratio of silt and clay naturally present in 60 and 40% respectively (Table 5-16). It is present in adequate quantity in P/H area and near Ganesh Bridge.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 7-3 View of Clayey Silt in P/H Area.

7.3 COARSE AGGREGATE

The rock units exposed in the Project Area are acidic in nature on the basis of silica contents i.e. granodiorite and granitic gneiss. Due to sliding of huge mass downslope, large material is deposited in foothills chocking the Hunza River. For coarse aggregate, three sites have been selected. Samples from slided mass, powerhouse area/river bed and Passu area have been collected and sent to CMTL WAPDA, Lahore to conduct different tests.

7.3.1 Passu Area

It is located about 35 km upstream of Attabad Lake along KKH near Passu village **(Photo 7-4)**. Bulk sample have been collected and sent to laboratory for testing. Petrographic analysis shows that marble is exposed. It consists of 97% of calcite, with specific gravity 2.84 and 0.37 water absorption, Los Angeles abrasion has uniformity of wear 0.20, crushing value 24, with flakiness index of 22. Sulphate soundness test result has weight percent loss 0.89.

The laboratory test results indicate that the rock mostly consists of calcite with no alkali silica reaction and no alkali carbonate reaction. This material has no deleterious quartz and tests results fall in permissible limit; therefore, it can be used as coarse aggregate for concrete with Ordinary Portland Cement.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 7-4 Exposure of Marble in Passu Village Area.

7.3.2 Power House Area

Large quantity of RBGM is deposited near old Chinese camp along old KKh route. Bulk sample from TP-2 has been collected and sent to lab for different tests **(Photo 7-5)**.

Photo 7-5 View of RBGM in TP-2 at P/H Area.

It consists of marble, granite, granitic gneiss, with some slate pieces. As per lab. test results, the material have specific gravity 2.78 with 0.33% water absorption. Los Angeles abrasion value with uniformity of wear is 0.20, crushing value is 27, and flakiness index is 21. Sulphate soundness value is 0.81 and average expansion for 28 days in accelerated mortar bar is 0.099, and point load index is 4.15 MPa (ch-5).

Petrographic analysis indicates that the rock is mostly granitic in composition and has more than 20% deleterious quartz, therefore, it cannot be used with OPC. To minimize the ASR, low alkali cement, slag cement or fly ash, pozzoloan can be used. Some chemical additives like

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

lithium nitrate or silica fume can also be used. The finalization of the additive material depends upon the other strength and expansion tests during concrete mix design. Moreover, all the values of other tests fall in permissible limit, therefore, it can be used as coarse aggregate material for concrete but not with OPC.

7.3.3 Slided Mass

Sample from TP-7 have been collected to conduct different lab tests. Lab testing program has been framed to check the suitability of this material. The description is given below: -

Petrographic analysis shows that rock is granodiorite and has more than 20% deleterious quartz and cannot be used with OPC. Point load strength is 5.94 with diametrically failure, specific gravity 2.72 and water absorption 1.04%. Los Angeles abrasion test show 0.41 uniformity of wear, crushing value 22 with flakiness index of 21. The value of Sulphate soundness test for this material is 1.87.

Photo 7-6 View of Slided Mass in TP-6 at Left Side Slope of Hunza River.

Higher Los Angeles abrasion, Sulphate soundness and presence of deleterious quartz values, show that this rock cannot be favorable for coarse aggregate material as in comparison with other two quarry site. Thus this material is not recommended as coarse aggregate for concrete works with OPC. This material can be used as coarse aggregate with slag cement, low alkali cement and by adding pozzoloan material to counter ASR.

7.4 BUILDING STONE

The granodiorite and granitic gneiss rocks are exposed in the project periphery, available for masonry works in sufficient quantities. More over, the large boulders, present in slided material can be used as rip rap material, to control the erosion/ wave action of water. This material has high strength UCS value ranges upto 72 MPa in TP-8. Similarly, the values of property index test, Los Angeles abrasion test fall in permissible limits. The slided mass may, therefore, be used as rip rap material.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

7.5 FILL MATERIAL

For protection works along slopes and structures, shoulder fill, construction of coffer dams, fill material of heterogeneous nature e.g. silty sand, sandy silt, gravelly sand etc. are available in river bed as well as in slided mass. These materials are present in ample quantities in the economic haulage of the Project Area.

Photo 7-7 Fill Material (Boulder and Gravels) in Slided Mass.

The test pits excavated in the powerhouse area / river beds show that large quantities of gravels and cobbles with subordinate sands are present. This materials satisfy the lab test program, therefore it might be used as fill material.

7.6 CEMENT AND STEEL

Cement and steel are required in adequate quantity for the construction of ALHPP. The cement should be supplied from nearby cement factory. The most nearer unit of cement is situated in Haripur/WAH areas includes Askari Cement, Wah cantt unit with capacity of 3500 ton/day and Fauji cement near Fateh Jang has two units; one with 3500 ton/day and other with 6700 ton/day.

These options can be considered for the supply of cement. The steel has to be transported from Rawalpindi to fulfill the requirement of the project. It is suggested that laboratory tests on representative samples should be carried out to determine the engineering characteristic of cement and steel prior to their use / procurement.

8 NEOTECTONICS AND SEISMIC HAZARD ANALYSIS

8.1 GENERAL

A large slided mass moved down and chocked the Hunza River and KKH for more than 2 km in January 2010 from right side near Attabad village. This large slide causes a 25 km long lake to develop upto Khyber village in Gojal. Due to excavation and development of channel through this slided mass, the level of lake decreases down and extension reduces up to Shishkat Bridge. This large mass slided down due to some regional stress operating in this region. To understand these regional forces and their effect and vulnerability of expected slope material to slide, a Neo-tectonic study has been conducted.

During the Feasibility Study, the colossal slide and as a result damping of Hunza River in 2010 has made the Neo-tectonic studies as core point. It is therefore, very important for the development of hydropower project in this area that understanding of Neo-tectonic setting should be explored to know the regional tectonic forces. Regional tectonic forces responsible for the massive slide are affecting Project Area severely as indicated by diverse features.

8.2 OBJECTIVES

Main objectives are:

- Evaluation of the regional tectonic setting of the area and recognition of fault (regional or local) which may act as a seismic source.
- Detailed investigation of the fault geometry, alignment, and structural deformations associated with these fault. These may include shear zones, fault bend folds, active slides and fault breccia.
- Recognition of active fault zones and their distinction from older, dormant fault zones.
- Assessment of the vulnerability of Neo-tectonic activity along the fault/slides around the Project Area so that the movement along the affected area may be predicted.
- Identification of deformation/displacement in recent deposits to evaluate the activity of area.

8.3 METHODOLOGY

An array of activities including literature review,image analysis,field studies and datacompilation are involved in Neo tectonic evaluation as per standard practices in Industry. These include:

- Collection of previous research on regional as well as on local geology, geomorphology and tectonics of Project Area.
- In-depth studies on satellite image analysis using GIS techniques by applying various image-enhancing techniques e.g. Digital Elevation Model (DEM) have been studied, the lineaments and faults on regional as well as on local scale have been recognized.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Detailed geological map of the Project Site, regional and local faults within the vicinity covering the upstream and downstream of the Project Area have been marked on GT sheets at scale of 1:50000 in the field area to understand the trend of regional tectonic forces.
- During field visit keen concentration has been given to characterize the kinematics of fault where possible e.g. sense of fault (Strike and Dip), alignment and type of fault, throw and heave, dip direction and other associated characteristics.
- Development of fault-source map indicating various regional scale faults that may contribute seismic affect in the Project Area.
- The relationship of older tectonic features to the recent ones.
- Field evidences of Neo-tectonic features have been captured in photographs including active slides, tiltness in recent deposits, folding, faulting, step fault, fault associated folding in recent deposits, topographic features including drainage pattern at slopes and abrupt shifting of river/stream course.

8.4 FIELD OBSERVATIONS

This study covers the 40 km upstream and 50 km downstream of the Project Site along both banks of the Hunza River. Different features related to Neo-tectonics activity have been observed during site visit. In this study the focus has been given to the recent deposits, at the both bank of river.

The main objective of the Neo-tectonic study has been to identify/observe the feature of active tectonic events occurred in recent past about 0.1 Million years ago. There are many field observations regarding the Neo-tectonic activity. Some of the Neo-tectonics features/observations are as under: -

- The tiltness in recent deposition, i.e. to study the slopes of gravels, clays, and sand layers w.r.t slope of the stream beds.
- Intersection of faults in recent deposits i.e. lacustrine deposits, terraces/ alluvial deposits or in any cultural features (houses, roads). The amount of displacement, Heave as well as Throw measurement, dip and strike of the fault.
- The presence of active slide zones.
- The displacement /uplift in fluvial as well as lacustrine deposits on each side of the lake/stream and magnitude of its displacement.
- Identify the zones of brittle as well as ductile deformation.
- To observe the movements along slicken sides / fault / joints blocks.
- The presence of hanging valley along the main streams.
- The presence of escarpment slope along the plain area.
- The presence of hanging valleys /cirques along main stream, in series and presence of waterfalls along it.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Folding/bending in the recent deposits (alluvium, morainic, lacustrine).

The Neo-tectonic features at the right as well as left bank of Hunza River in different villages from upstream to downstream **(DRW No: AFS-GE-318 to 320)** are described below: -

8.4.1 Passu Village:

Passu is one of the largest village in Gojal valley situated at the right bank of Hunza River along KKH about 35 km from Attabad Site. The great Passu Glacier, 56 km in length is present near the village. Many deformational evidences have been observed in recent deposits along the road.

- 2-3 km upstream of Passu village

N 4038610.325 m

E 489292.583 m

El. 2470.03 m.a.s.l

The coordinates measured by mobile topographer application.

A large deposit of RBGM material is present along the right side slope of the river along KKH. This material consists mostly of gravel, cobble, and pebbles with subordinate sandy material. Some inclinations in these deposits have been observed along roof and sole beds. This inclination varies from 15° to 35° layer-by-layer **(Photo 8-1).**

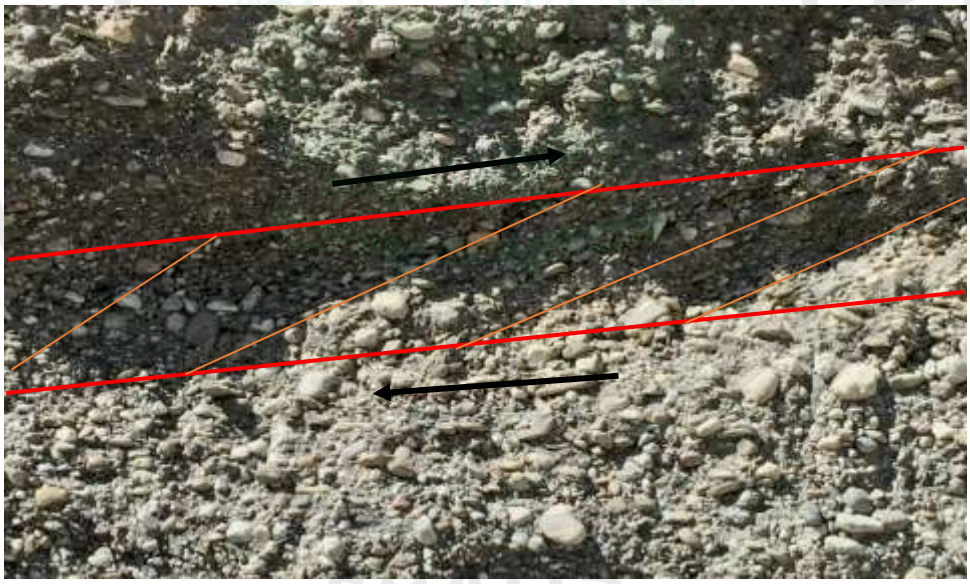

Photo 8-1 Inclined Gravel Layers under Effect of Shearing

Some shearing effects have been chronicled along these planes in numeral layers. This shows that the area is tectonically active.

The clay deposits are overlain by morainic material of Batura Glacier. The clay deposits are tilted upward at an angle ranging from 10° - 15°. The area has undergone compressional regime, which uplifted the clay beds **(Photo 8-2)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 8-2 Recumbent Fold Strata with Crenulation in Limbs in Clay Strata.

The clayey strata is folded with straight horizontal limbs and horizontal hingline. This shows that the horizontal compressional stress is applied on this material that turned this unit into folded strata **(Photo 8-3).** Many micro folds (crenulations) in both limbs of fold are present. The Hinge area toward outer layers point out, that intense compressional stress is applied to the strata.

Photo 8-3 Stylolite/Pressure Solutions in Clay Strata.

The strata shows some stylolite structures that are formed by expulsion of water through pressure solutioning. Alignment of wavelength and geometry of hinge area indicates that the compressional stress is applied horizontally **(Photo 8-4)**. This shows that the recent stresses are functioning in this area.

Many joints are developed in the clay beds showing that there are relative movement in blocks along the plane, which might be acted as micro faults **(Photo 8-5)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The relative movement of hanging wall block moves down relative to the footwall block, signposted the development of normal fault.

Photo 8-4 Micro Fault in Clay Beds.

At the same location there are cross cutting faults, dipping towards each other in clay beds. The block between two micro faults moves downward forming Graben structure while the block, that cannot move forming Horst structure **(Photo 8-5)**.

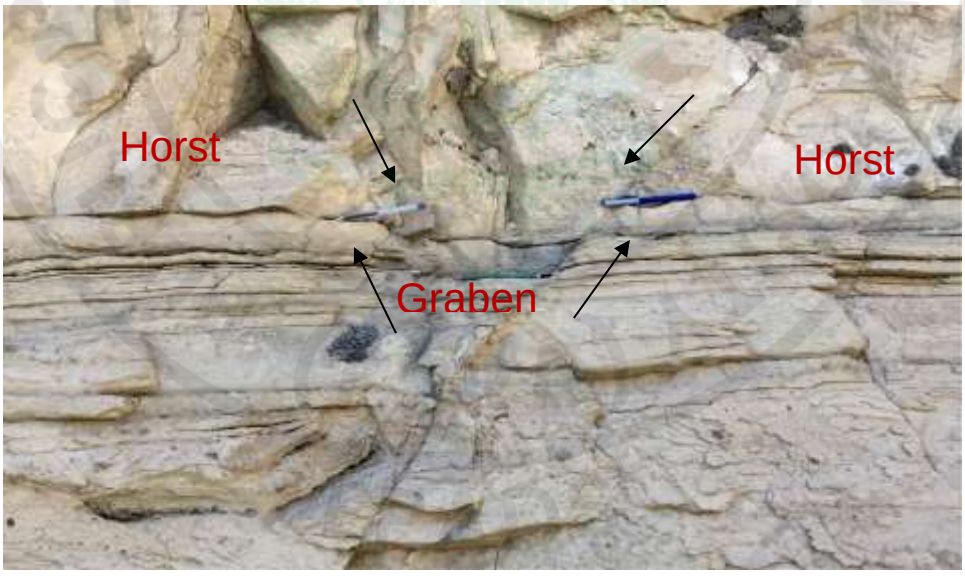

Photo 8-5 Horst and Graben Structure along Micro Fault in Clay Beds.

The formation of these structures in clay beds show that there is relative movement along the micro faults in recent deposits.

The development of these normal fault systems in such compressional regime indicates that these deposits are under such environment where two thrust faults dipping toward each other.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The up thrown block between these two faults undergone extensional regime where normal faults are developed. This indicates that this area is under active tectonics regime.

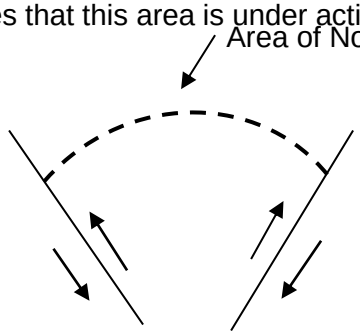

Figure 8-1 Development of Normal Faults under Compressional Regime.

8.4.2 Road Section from Murradabad to Hussani Village:

Coordinate

N	4033080.557 m
E	489417.275 m
El.	2656.69 m.a.s.l

Just upstream of Hussaini village a large mass of ABGM and brecciated rock is exposed along the road. It is present in the alignment of thrust fault where crushed marble is in contact with Passu Slates. The faulted contact between slate and marble is well exposed along road **(Photo 8-6)**.

Photo 8-6 View of Brecciated Rock Upstream of Passu Village.

In this area two faults are intersecting each other; one is striking N60°E and dipping 40°NW while other is striking NW and dipping NE **(DWG No: AFP-GE-3180)**. Due to these faults discrete hillocks have formed with thin overburden overlain by fault breccia. At few feet away from breccia, a slided material consists of ABGM is present along road. Apparently this material

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

seems to be stable but in excavated portion, it is folded. Compressional forces are responsible for this deformation exposed at slope **(Photo 8-7)**.

Photo 8-7 View of Folded ABGM just Upstream of Passu Village.

Rock (Passu Slates) is locally folded, some shear joints along which the cleavage plane (originally bedding planes) across shear joint has different dip values. The overall strike of slates is NW and dipping in NE but along this shear joint some movement took place and the value of dip changes from SW to NE **(Photo 8-8)**. Change of sense of dip along the shear joint shows that some shear forces are active in the area. The developments of such joints indicate the brittle deformational style.

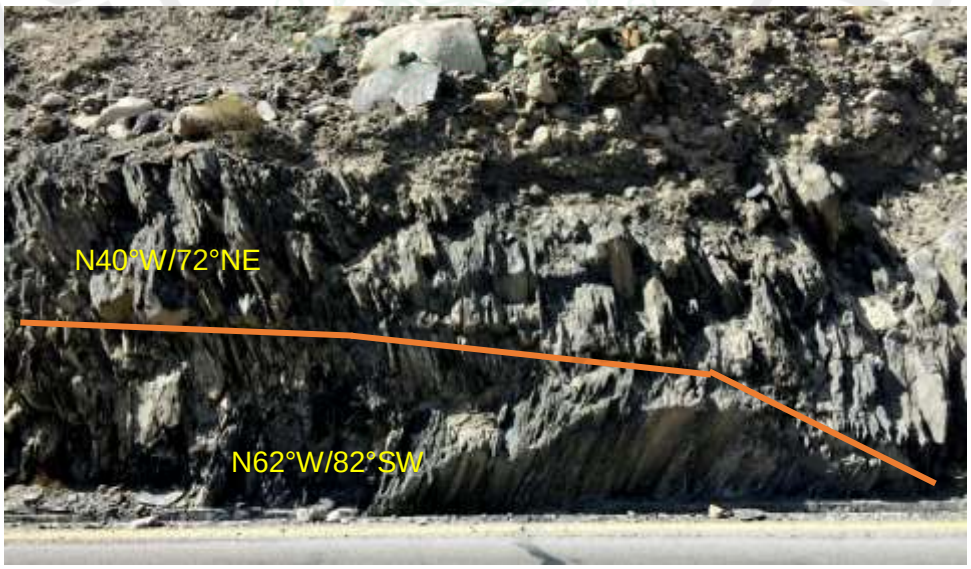

Photo 8-8 Change of Dip along Shear joint.

8.4.3 At Sarat Village:

Coordinates:

N 4018254.850 m

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

E 481549.816 m
El. 2371.35 m.a.s.l

Due to Salmanabad slide in 1858, a large lake developed in upstream reaches. The depositional clayey silt can be seen on both bank of Hunza River. Due to operational neo-tectonic forces, deformation including folding, jointing, micro faulting have been developed in these deposits.

Both vertical and oblique joints can be seen in clayey silt at right side near Sarat Suspension Bridge. The strike and dip values of vertical and oblique joints are N38°W/87°NE and N32°E/63°SE respectively **(Photo 8-9)**.

Photo 8-9 View of Vertical and Oblique Joints in Clayey Silt at Sarat Village.

Clayey silt beds are striking N 80°E and dipping 18°NW at the left side of road to Sarat Village while at the right side of the road these beds have strike N 32°E and dipping 9°SE **(Photo 8-10 & 8-11)**.

Photo 8-10 Tiltness in Clayey Silt Beds, Left Side of Road at Sarat Village.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The strike of the beds is NE while the dip is in opposite direction, indicating that it forms some sort of antiform. Formation of antiform in recent deposits clearly indicates that lateral shear compressional force are operational in this area.

Photo 8-11 Tiltness in Clayey Silt Beds, Right Side of Road at Sarat Village.

Just downstream of Sarat village near the Suspension Bridge, fault breccia is exposed along the river showing the alignment of fault.

Photo 8-12 Folded and Sheared Clayey Silt at Sarat Village.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 8-13 Sheared and Smeared Clayey Silt at Sarat Village.

Photo 8-14 Fault Breccia just D/S of Suspension Bridge at Sarat Village.

Folding, jointing, smearing and shearing of clayey silt **(Photo 8-12, 8-13, 8-14)** deposits show some lateral stresses are actively operating in this area. The active slides and rolling down of brecciated material from this slope indicate that it is tectonically active area.

8.4.4 Inside Tunnel 2

Many cracks/joints are going to develop in the concrete especially in crown area in tunnel-2. The pattern of the cracks indicates stress release and shear oblique joints **(Photo 8-15)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 8-15 View of Recently Generated Joints Tunnel-2.

As far as geological condition is concerned, this portion of tunnel in is under influence of two faults **(DWG No: AFP- GE- 319)**. Rock is highly crushed, rolling down of boulders is quite common along these active faults. The active tectonic forces are responsible for the development of fractures in this terrain. The same features can also be noted in concrete area in between tunnel 2 and 3 **(Photo 8-16)**.

Photo 8-16 View of Recently Generated Joints between Tunnel-2 & 3.

The concrete slab fractured between tunnel 2 and 3. It is evident that some tectonic forces are recently operative in this area.

8.4.5 Power House Area

In powerhouse area near helipad along old KKH, clayey silt is present where Chinese Camp was established. The clayey silt has been deposited after river choking due to Salmanabad

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

slide. Due to operational compressional stresses, some deformations including faulting, shearing, folding, and tiltness in clayey silt have been observed.

Photo 8-17 Micro Thrust Fault in Clayey Silt Beds near Helipad.

The relative movement of both blocks against fault plane indicates compressional environment, moved the hanging wall block upward **(Photo 8-17)**.

Photo 8-18 Inclination of Clayey Silt near Helipad.

The clayey silt beds are well exposed at the left side of Hunza River near Sarat Bridge. The clayey silt beds are well jointed and tilted upward at an angle ranging from 10° to 15° **(Photo 8-18)**. The inclinations of the beds in recent soil are active tectonic features.

Near old Chinese Camp, at powerhouse area, the clayey silt is folded **(Photo 8-19)**. Folding in recently deposited clayey silt may be the result of slipping along fault plane under regional compressional shear forces.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 8-19 Folding in Clayey Silt near Helipad/Powerhouse Area.

Near the SCO building, along old KKH, near tunnel-1, some cracks are going to develop in recently deposited material. The development of joints is mostly parallel in nature but occasional cross cutting joints also present **(Photo 8-20)**.

Photo 8-20 Development of Parallel Joints near SCO Building.

8.4.6 At Murtazabad- Shahyar Road:

Coordinates:

N	4016299.113 m
E	465418.47 m
El.	2095 m.a.s.l

Just crossing the Murtazabad to Shahyar Bridge, a thick alluvial deposit consists of gravels, cobbles, pebbles interbedded with silty sand is exposed. This material moved upward against fault plane and formed fault bend fold **(Photo 8-21)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 8-21 Inclination in Clay Silt and Gravels.

The beds are tilted at an angle of 22° to 30°. Many micro fault in sand beds have been observed in hinge area of the fold. The ramp and flat geometry have NE striking and dip SE **(Photo 8-22)**.

Photo 8-22 Ramp and Flat Geometry along Fault.

Some micro faults have been observed in this alluvium. Step faulting on micro level is well preserved in sandy material **(Photo 8-23)**. This alluvium is overlain by morainic material. Same joint pattern is going to be develop in it. Some open joints ranging from 10 cm to 150 cm have been observed there. All these features indicate that the tectonic forces are active in this area.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 8-23 Development of Micro Faults in Sand.

8.4.7 In Tashot Village:

Coordinates: N 4012830.531m
E 462157.244m
El. 2111.0 m a s l

After crossing suspension bridge near Tishot Bridge, a thick deposit of RBGM and clayey silt are exposed along the road toward Phakhar village. Due to some recent activity, clayey silt has displaced and smeared along micro fault.

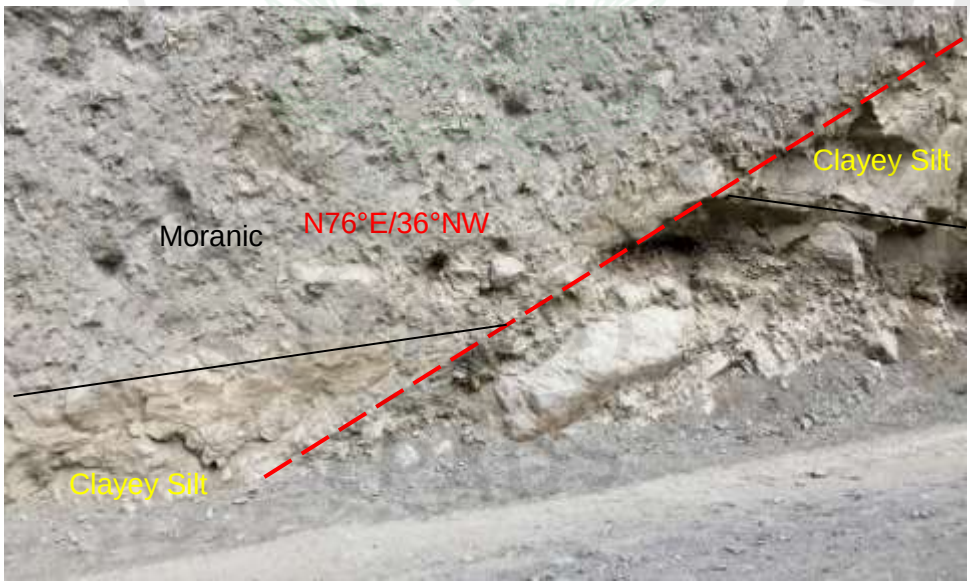

Photo 8-24 Development of Micro Faults in Clayey Silt.

Upward inclination of 6°in recent RBGM in measured along the road **(Photo 8-24, 8-25)**.

8.5 SEISMIC HAZARD ANALYSIS

The quantitative and qualitative seismic hazard analyses presented in this study preceded by a detailed appraisal of the structure, geodynamics and neotectonics, to characterize the on-site and regional tectonic scenario to assist in proposing a suitable earthquake resistant design. This study has used the seismic source characterization deduced in the accompanying Neo-tectonic studies and calculated the earthquake potential hazard and related ground motions as presented in this report.

8.5.1 PROBABILISTIC HAZARD ANALYSIS

Both PSHA and DSHA were carried out using EZ-FRISK software Version 7.65 developed by Risk Engineering Inc. USA. The latest version of R-CRISIS Software version 21.1.1 developed by PEER, USA has also been used during the current study. The purpose of using both software has to cross check the validation comparing the quality of the seismic hazard analysis of the two software for the project. During the study it has been found that Ez-Frisk software is more standardized as compared to R-CRISIS software in quality of analysis as well as the smart outputs of the analyzed results. Therefore, Ez-Frisk software has been preferred and used in the in the final analysis.

Important input parameters for different seismic zones used in probabilistic approach are presented in **Table 8-1**. It is assumed that weir foundation will be placed on gravelly soil (alluvium), therefore, the site condition has taken as gravelly soil with average shear wave velocity at 30 meters depth (V_{s30}) of 450 m/sec for soil site (alluvium) and 760 m/s for rock sites. The mean total hazard curve obtained by giving equal weighting to all the Five NGA W2 Ground Motion Prediction Equations.

The total hazard curve obtained for the Project Area is shown as **Figure 8-2** and the total mean Hazard Spectra showing combination of all used Ground Motion Prediction Equations for ALHPP is presented as **Figure 8-3**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 8-1 Seismic Source Parameters for Probabilistic Analysis

Source Zone	Seismic Source Zone	Min. Magnitude Mw	Activity Rate / Year	β	Max. Magnitude Mw
1	Karakorum	4.0	1.929	1.120	7.3
2	Nanga Parbat	4.2	1.112	1.101	7.0
3	Western Himayan	4.1	5.339	1.44	7.0
4	Hindukush	4.2	59.107	1.20	8.0
5	Kashmir Himalaya	4.2	7.143	1.13	7.8
6	Kohistan	4.1	10.500	1.07	7.5

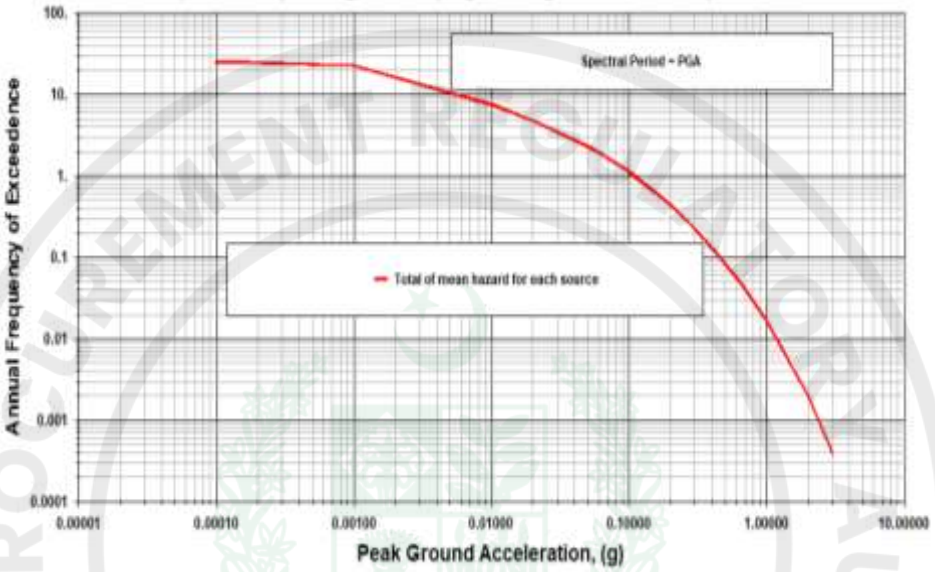

Figure 8-2 Total Hazard Curve for ALHPP.

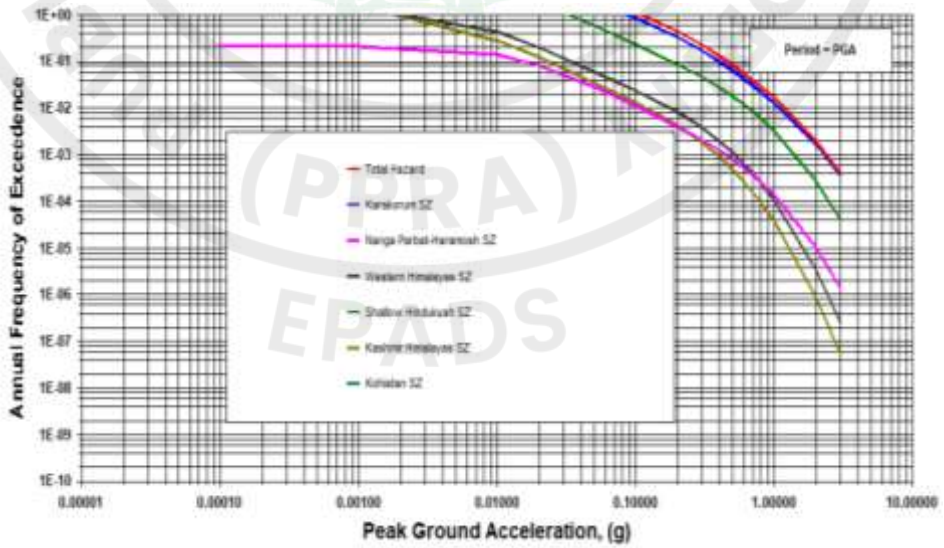

Figure 8-3 Earthquake Hazard by Seismic Sources, Showing Spectral Response.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

8.6 DETERMINISTIC SEISMIC HAZARD ANALYSIS (DSHA)

The capability of the faults to generate earthquakes is ascertained by means of analysis of historical and instrumental seismic data and geological criteria such as rupture length – magnitude relationship or fault movement – magnitude relationship.

The main tectonic features around the Project Site within a radius of 200 km which could be controlling the maximum earthquake hazard are as follows:

- Hunza Fault
- Main Karakoram Thrust (MKT)
- Main Mantle Thrust (MMT)

Empirical correlations have been developed between maximum potential of a fault and key fault parameters like rupture length, fault area, fault displacement and slip rate. Out of these fault parameters, only fault lengths are known with sufficient accuracy. For the faults around the ALHPP site, the half rupture length of the faults has been taken for determination of maximum potential magnitude. The maximum earthquake magnitude (in moment magnitude M_W) of each of the fault calculated using Wells & Coppersmith (1994) relationship between fault rupture length and magnitude and the input data given in **Table 8-2** has been used for deterministic approach.

Table 8-2 The Controlling Faults with Quantitative Features (input values of DSHA)

Controlling Faults	Fault Type	Fault Rupture Length (km)	Distance (km)	Maximum magnitude potential	
				Catalogue data	Conservatively Assigned
Hunza Fault	Thrust	5 inferred	1.4	6.1	6.7
MKT	Thrust	200	32	7.0	7.6
MMT	Thrust	260	71.69	6.9	7.6

Ground motion prediction equations developed under the Next Generation Attenuation (NGA) West 2 Project of PEER (Pacific Earthquake Engineering Research Center, University of California at Berkeley, USA) are used to obtain the median and median plus-one percentile levels of Peak Horizontal Ground Acceleration (PGA) in deterministic approach.

The NGA equations are developed using a large worldwide database of strong motion recording of earthquakes of magnitude 4-8 and distances ranging from 0-200 km in accordance with ICOLD Guidelines. The NGA equations are preferable over the older equations for the evaluation of seismic hazard particularly in the near field as these are based on a broad spectrum of data recorded in the near field. The same attenuation equations were used for the PSHA approach too.

For all the seismic sources, thrust rupture mechanism has been considered. It is assumed that dam foundation will mainly be placed on gravelly soil therefore the site condition for weir has been taken as gravelly soil with average shear wave velocity for top 30 meters (V_{s30}) of 760 m/sec. The depth to basement rocks (Z_{25}) is taken as 5 km. The PGA g values have been calculated using the latest 5 sets of NGA West 2 Ground Motion Prediction Equations (GMPEs).

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Input values in Deterministic Seismic Hazard Analysis (DSHA) are given in **Table 8-2**. The analyzed results obtained through DSHA are presented in figures.

8.7 DETERMINISTIC RESPONSE SPECTRA

Deterministic Response Spectra for Safety Evaluation Earthquake (SEE) at 50th percentile and 84th percentile levels over the Five NGA West 2 equations are shown in **Figure 8-4 & 8-5** respectively.

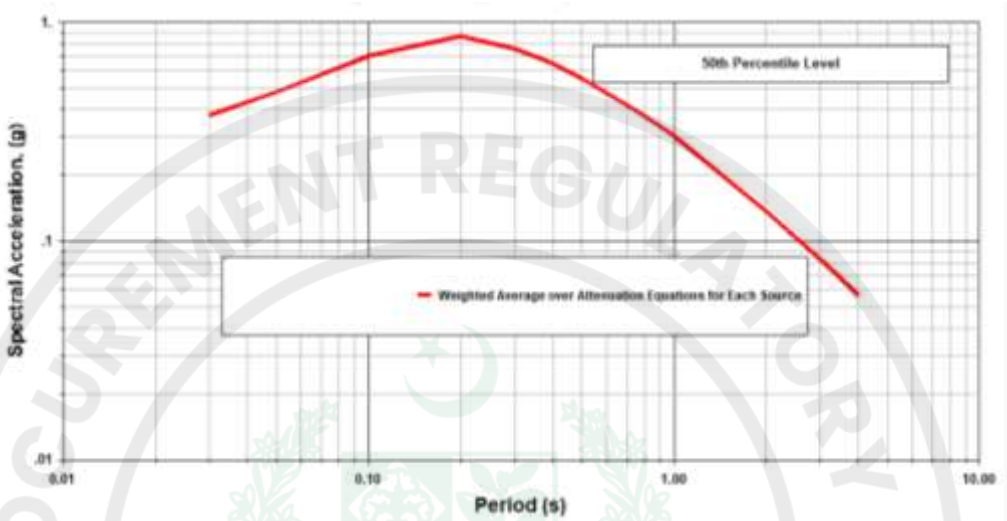

Figure 8-4 Deterministic Spectra at 50th Percentile Level Weighted Average

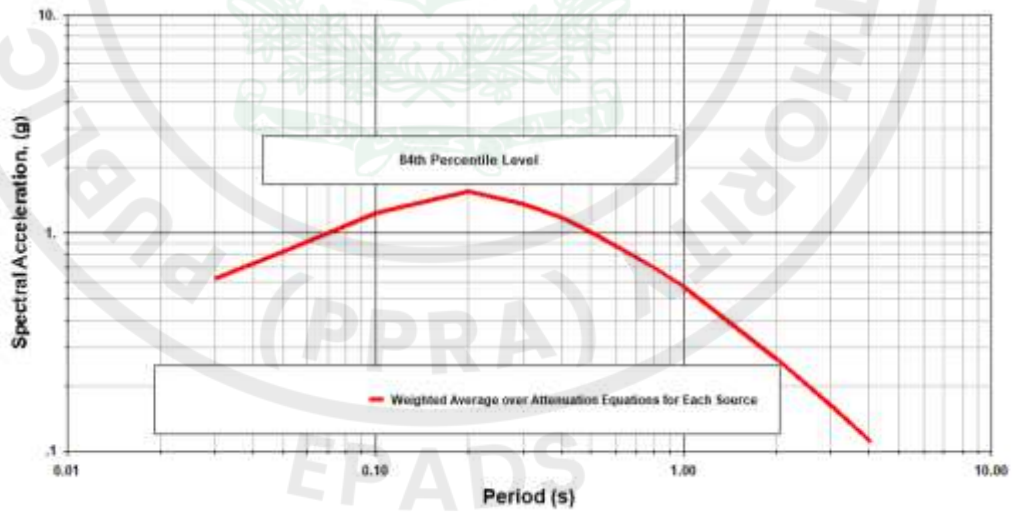

Figure 8-5 Deterministic Spectra at 84th Percentile

8.7.1 Deterministic Pseudo Spectral Acceleration (PSA)

Pseudo spectral acceleration has been worked out using the latest version of R-CRISIS software. Pseudo spectral acceleration Vs time is given in **Figure 8-6**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

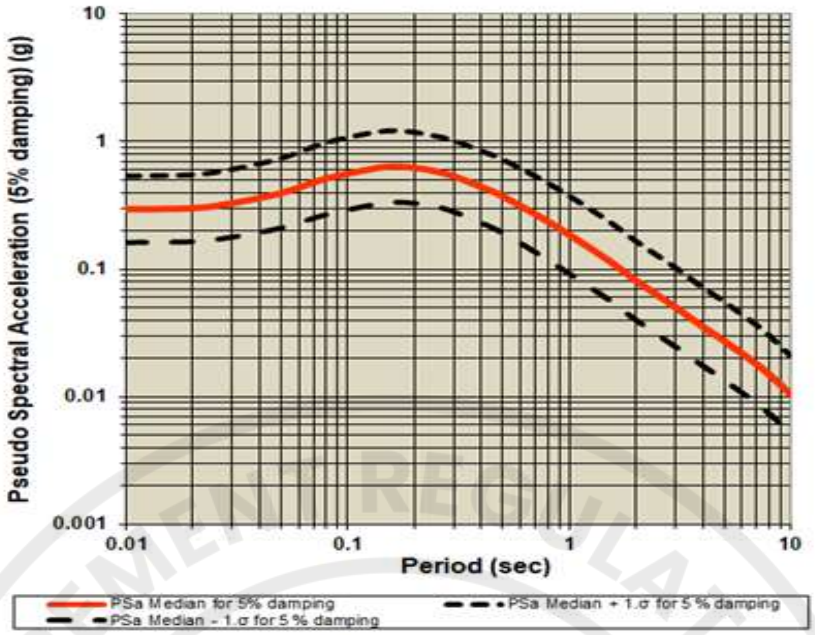

Figure 8-6 Deterministic pseudo Spectral Acceleration (g) at 5% Damping.

8.8 SELECTION OF SEISMIC DESIGN PARAMETERS

8.8.1 Safety Evaluation Earthquake (SEE)

As per ICOLD guidelines (2016) the Safety Evaluation Earthquake (SEE) will produce the maximum level of ground motion for which the dam should be designed or analyzed. For dams whose failure would present a great social hazard, the SEE will normally be characterized by a level of motion equal to that expected at the dam site from the occurrence of deterministically evaluated MCE or of the probabilistically-evaluated SEE earthquake ground motion with a very long return period, for example 10,000 years for high consequence large dams. Depending on the circumstances e.g. the importance of the dam, the consequences of a dam failure, it is recommended to design safety-critical elements such as the bottom outlet and/or spillway gates for the SEE. It will be required at least that there is no uncontrolled release of water when the dam is subjected to the seismic load imposed by the SEE.

As per the latest ICOLD Guidelines, for medium consequence dams, median value (50^{th} percentile level) is recommended whereas for high consequence dams, the SEE ground motion parameters should be estimated at median plus one (84^{th} percentile level) if developed by a deterministic approach and need not have a mean annual exceedance probability (AEP) smaller than 1/10,000 if developed by a probabilistic approach. For a particular project of importance such as hydropower project, optimum percentile level may be any optimum percentile level between 50^{th} percentile level to 95^{th} percentile level. For ALHPP, 66^{th} percentile level has been worked out and the same is recommended.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

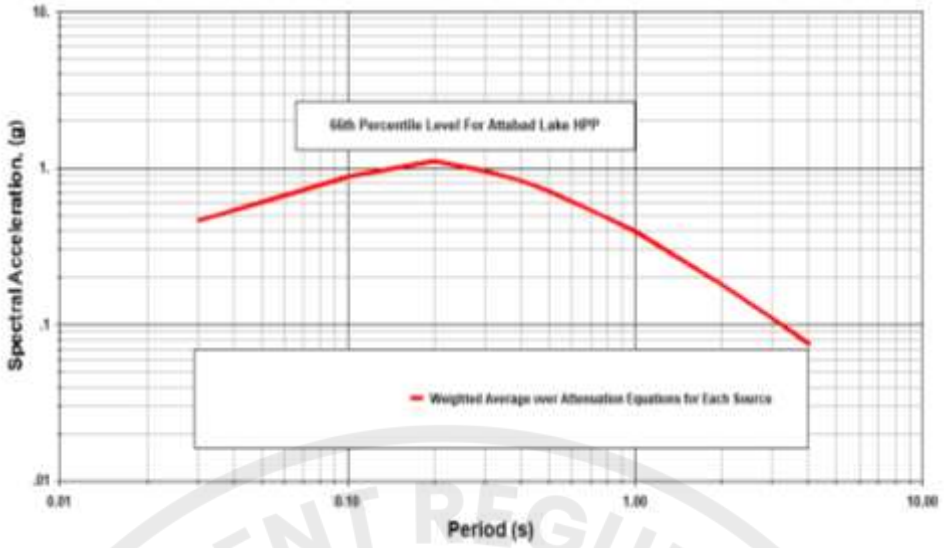

Figure 8-7 Deterministic Spectra at 66th Percentile Level of SEE.

8.8.2 Operating Basis Earthquake (OBE)

The Operating Basis Earthquake (OBE) represents the level of ground motion at the dam site at which only minor damage is acceptable. In theory the OBE can be determined from an economic analysis, but this is not always feasible and, in many cases, it will be appropriate to choose a return period of about 145 years (i.e. a 50 % probability of not being exceeded in 100 years). The dam, appurtenant structures and equipment should remain functional and damage easily repairable, from the occurrence of earthquake shaking not exceeding the OBE.

Since the consequences of exceeding the OBE are normally economic, the circumstances in a particular case may justify use of a more severe or less severe event for the OBE. The resulting return period depends on prevailing conditions.

Because of the above definition, the OBE is the best determined by using probabilistic procedure. OBE ground motions are significantly lower than those for SEE.

8.8.3 Uniform Hazard Spectra (UHS)

Uniform hazard spectra for ALHPP for OBE (145 year return period), DBE (475 year and 2475 years return period) and SEE (10,000-years return period) are presented as **Figure 8-8.**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

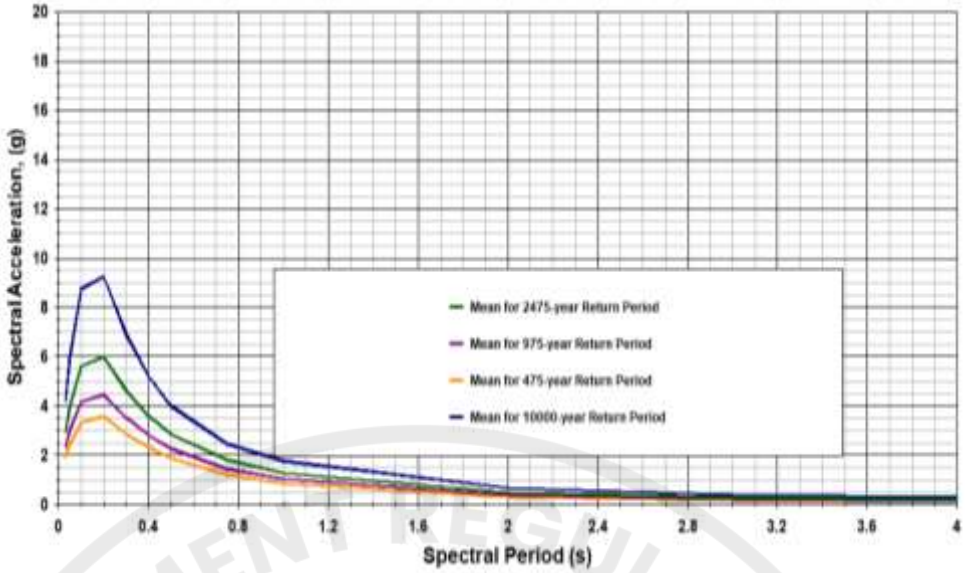

Figure 8-8 Uniform Hazard Spectra (UHS) showing mean hazard for various return periods.

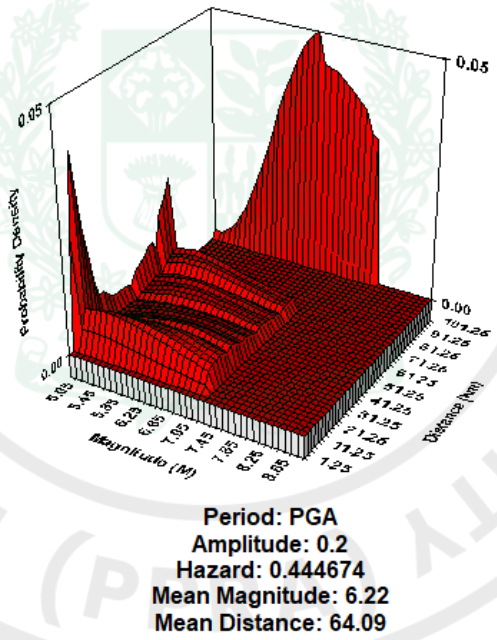

Figure 8-9 Deaggregation of Mean Hazard, Mean Magnitude and Mean Distance.

8.9 CONCLUSION AND RECOMMENDATIONS

Based on the analysis results, the following earthquakes design parameters are concluded and recommended for ALHPP.

<u>Operation Basis Earthquakes (OBE):</u>

OBE at return period of 145 years is recommended as follows:

OBE Horizontal = 0.24 g

OBE Vertical = 0.17 g

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Safety Evaluation Earthquakes (SEE):

For the design of dam / weir, the following PGA 'g' values for SEE (Safety Evaluation Earthquakes) are recommended:

SEE Horizontal = 0.44g

SEE Vertical = 0.29g

For the design of appurtinent structures including spillway, the following PGA 'g' values for SEE (Safety Evaluation Earthquakes) are recommended:

SEE Horizontal = 0.38g

SEE Vertical = 0.26g

9 CONCLUSIONS

- The Project Area lies in Karakorum Block, where rocks of meta igneous provenance are exposed. The rock units represent acidic igneous rocks including Granodiorite and Granitic Gneiss.
- The Project Area lies in the vicinity of collisional tectonic belt, bounded by Main Karakoram Thrust (MKT) in south and Karakorum Fault (strike slip) in northeastern margin. Many local as well as regional faults are present in Project Area.
- Different surface and subsurface investigations including surface geological mapping, drilling, neo-tectonic studies and seismic hazard analysis have been carried out during Feasibility Study. It is observed that overall the area is tectonically disturbed, many deformational features are illustrious of recent operative compressional forces in recently deposited material.
- Different laboratory tests regarding geotechnical parameters for design and foundation evaluation have carried out in the field and in laboratory. The rock core samples as well as soil samples (from UDS and SPT) from different test pits regarding different structures and borrow area have been carried out in Central Material Testing Laboratory (CMTL) Lahore.
- The geotechnical investigations carried out during Feasibility Study indicates that weir is founded at overburden material consist of slided mass. High permeability values encountered during drilling in all borehole is indicative of gaps/cavities in subsurface. One of the major task is to control the seepage through slided mass for the stability of weir and other appurtenant structures. Slope stability at both abutments of weir and sediment flushing channel is very important and crucial task in this regard.
- All the appurtenant structures i.e. sediment flushing channel, power tunnel, surge shaft, penstock and power house are proposed on left side of Hunza River.
- During the Neo-tectonic studies it is observed during field work that there are many active surface geological features regarding the recent tectonic activities operating in the vicinity of the Project Area. These features have been incorporated as parameters in calculation of Peak Ground Acceleration (PGA) “g” value in Seismic Hazard Analysis.
- Both fine and coarse aggregates for construction of overtopping concrete weir and other associated structures are present in the vicinity of Project Area in ample quantities. Clayey silt for blanketing/impervious material, coarse aggregate and rip rap have been investigated and proposed as barrow area while sand and fill materials are proposed to be excavated from river bed.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

10 RECOMMENDATIONS

- As active tectonic forces are operative in this area, it is quite important that all the structures should designed according to peak ground acceleration “g” value calculated by seismic hazard analysis.
- The active tectonic forces are responsible for the rolling down of Attabad Slide. Some additional investigations should be carried out at right side slope. At different locations installation of inclinometers and fixation of telltales (Glass strips)/movement pins should be carried out during DED to observe the ground motion.
- Clay blanketing/grout curtain may be required to control the seepage especially through the foundation of weir and sediment flushing channel.
- Special attention should be given for the stabilization of slided mass at both banks of Hunza River, especially along sediment flushing channel and weir area.
- Ample quantity of Angular Boulder Gravels (ABG) present in slided material falls in permissible limits as perceived by laboratory testing. It can be used as rip-rap material to stabilize the slope in upstream area.

1 INTRODUCTION

1.1 GENERAL

Attabad Lake Hydropower Power Project (ALHPP) is proposed on Hunza River, a left tributary of Gilgit River. A large slide occurred on January 4, 2010 from right side slope of Attabad, chocked the Hunza River. The total height of the slide as estimated by GSP (Geological Survey of Pakistan) was about 100 m and the blocked length of river was about 2 km that destroyed 1.3 km of Karakorum Highway (KKH) (ISSMGE Bulletin: Volume 4, Issue 3 Page 21). Due to development of lake, WAPDA Authority planned to utilize this potential for Hydropower Development. Firstly, GB local consultants conducted feasibility study. The study was lacking in many aspects including geotechnical investigations, laboratory testing, layout planning, pros and cons of sliding, Neo-tectonic study and environmental issues. The Feasibility study has been submitted to Hydro Planning, WAPDA for comments and updating.

The Hydro Planning WAPDA entrusted to carry out the feasibility study of Attabad Lake HPP. During the detailed analysis and investigations, it is estimated that lake potential of 0.1MAF (125Mm^3), can be utilized to generate about 54 MW. The coordinates of weir site are 484036.834m E and 4018143.837m N with bed elevation 2368 m a s l from river bed**(DRW No: AFS- WR - 403)**

The proposed weir site is located about 20 km upstream of Aliabad (Central Hunza), near Attabad village, District Hunza. The site is accessible by metaled road from Gilgit city, the capital of Gilgit-Baltistan. From Islamabad, the site is reachable through Karakorum Highway (KKH) by covering about 750 km. It is also accessible through PIA air plane from Islamabad to Gilgit and thereon to Hunza via Karakorum Highway **(DRW No: AFS- GN- 102).**

Geologically site is located in Karakorum Block (KB) further North of Main Karakorum Thrust (MKT). The KB consists of Sedimentary, Metasedimentary, Igneous as well as Metamorphic Rock, throughout its extension from Karakorum Fault in the East, Chaman and Herat Fault in West (Zanchi 1993) ranging in age from Precambrian to Cretaceous. The overburden material, consist mainly of Angular Boulder Gravel with Sand and appreciable amount of fines (ABGM) and Rounded Boulder Gravels with Sand and appreciable amount of fines (RBGM). The talus deposits are main constituents of ABGM and well developed mostly in Shamshal valley and along Hunza River in upstream reaches. There are many evidences (the deposition of clayey silt along both banks of Hunza River) along the road indicate that the river might be chocked many time in recent past. Prior to Attabad slide, the slope failure occured at Salmanabad in 1958 and chocked the Hunza River.

The topography and geological conditions present in this valley indicate that it is glacial originated valley modified later on by river system. There are many glaciers that feed the Hunza River, from South to North i.e. Hassanabad, Gulmit , Gulkin , Passu and Batura Glaciers, from right side and Shamshal Valley Glacier from left side. Morphologically the valley is lithological as well as structurally controlled. Weak lithology i.e. slates as well as fault system attributed for the development of present shape of the Hunza valley in upper reaches and near MKT.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

This Report is mainly based on the annotations observed during field visit at both banks along Hunza River and its tributaries mainly originated from glaciers. During this visit the main concentration was to observe the deformation in recent deposits mostly in rounded boulders gravel with sand and appreciable amount of fines (RBGM), sand, clay and silt etc. Due to chocking of river and development of lake, sedimentation took place at both banks of the river. As a result, of collision between Indian & Eurasian Plates, a continuous application of stress resulted in deformation of variegated levels.

1.2 SCOPE OF WORK

During the Feasibility Study, the colossal slide and as a result damping of Hunza River in 2010 has made the Neo-tectonic studies as core point. It is therefore, very important for the development of hydropower project in this area that understanding of Neo-tectonic setting should be explored to know the regional tectonic forces. Regional tectonic forces responsible for the massive slide, affecting Project Area severely as indicated by diverse features.

The area under study has covered by the two Nos of GT sheets 42 L/15 and 42 L/11 by Survey of Pakistan (SoP) at a scale of 1:50,000, covering the area upstream and downstream of slide mass.

1.3 OBJECTIVES

Main objectives are:

- Evaluation of the regional tectonic setting of the area and recognition of fault (regional or local) which may acted as a seismic source.
- Detailed investigation of the fault geometry, alignment, and structural deformations associated with these faults. These may include shear zones, fault bend folds, active slides and fault breccia.
- Recognition of active fault zones and their distinction from older, dormant fault zones.
- Assessment of the vulnerability of neo-tectonic activity along the faults/slides around the Project Area so that the movement along the affected area may be predicted.
- Identification of deformation/displacement in recent deposits to evaluate the activity commenced in the area.

1.4 METHODOLOGY

An array of activities including literature review, image analysis, field studies and data compilation are involved in Neo tectonic evaluation as per standard practices in Industry. These include:

- Collection of previous research on regional as well as on local geology, geomorphology and tectonics of Project Area.
- In-depth studies on satellite image analysis using GIS techniques by applying various image-enhancing techniques e.g. Digital Elevation Model (DEM) have been studied; the lineaments and faults on regional as well as on local scale have been recognized.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Detailed geological map of the Project Site, regional and local faults within the vicinity covering the upstream and downstream of the Project Area have been marked on GT sheets at a scale of 1:15000 in the field to understand the trend of regional tectonic forces.
- During field visit keen concentration has been given to characterize the kinematics of faults where possible e.g. sense of faults (Strike and Dip), alignment and type of fault, throw and heave, dip direction and other associated characteristics.
- Development of fault-source map indicating various regional scale faults that may contribute seismic affect in the Project Area.
- The relationship of older tectonic features to the recent ones.
- Field evidences of Neo-tectonic features have been captured in Photos including active slides, tiltness in recent deposits, folding, faulting, step fault, fault associated folds in recent deposits, topographic features including drainage pattern at slopes and abrupt shifting of river/stream course.

2 REGIONAL GEOLOGY

2.1 GENERAL

Information and data relating to Regional Geology of Project Area is taken from already published literature and research papers. The catchment area lies in KB where snow covered peaks are quite common. The geological features in 40 km upstream and 50 km downstream of the Project Area have been studied in detail. In the Project Area many neo-tectonic features have been observed/recorded in the recent deposits which indicate that the regional tectonic forces are operating there.

The Project Area lies in the KB bounded in north by Central Pamir through Rushan Pshart Suture, in east by Karakorum Fault, in the west by Herat Fault and in south by Kohistan Island Arc (KIA) through MKT (Pashkov & Shvol'man, 1979 & 1981). The KB have classified as a part of Gondwana land in pre-collision history. The rocks of KB have stratigraphic association with rocks of Indian Plate as indicated by Paleozoic to Mesozoic sequence of both plates. It is likely to be considered that Karakorum Micro Plate and Indian Plate were united till Mesozoic Era.

The stratigraphic sequences of the Karakorum Plate are metamorphic equivalent of sedimentary rock in Indian Plate shows that both plates have pre-collision similarities. Also the Karakorum Plate consists of Sedimentary (well exposed in Chitral Area along Mastuj River), Ignoeus Rocks (Karakorum Batholith) and Metamorphic Rock (slates, schist and marbles).

The rocks of KB include a thick sedimentary cover, which is mainly Paleozoic in the western termination and Permian to Cretaceous in the central and eastern area. In the Hunza valley, the cover consists of a thick pile of Permian-Cretaceous sediments cropping out north of the Karakorum Axial Batholith (KAB). It separates the sedimentary cover to the north, named North Karakorum terrain by Searl (1991), from high to low grade metamorphic present south of the KAB just north of the MKT.

2.2 STRATIGRAPHIC SEQUENCE

The area under study mostly includes part of the Northern Karakorum Terrain, which comprises intensively folded and thrusted sedimentary rocks with a very low metamorphic imprint, locally reaching low grade conditions (Zanchi,1993). The Lower Permian to Upper Cretaceous succession of the North Karakorum represents one of the few terrains which escaped strong metamorphism during the Indian-Eurasian collision, thus permitted a detailed reconstruction of its stratigraphic framework **(DWG No: AFS-GE-291)**. Plutonic bodies mainly of mid-Cretaceous age intruded the sedimentary cover forming a discontinuous granitic belt developed about 100 km north of the KAB. Four main tectonic units have recognized in the Project Area (Gaetani et all., 1990). These include;

- Misgar Unit
- Sost Unit

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Gojal Unit
- Karakorum Axial Batholith (KAB)

The brief descriptions of these units are given below;

2.2.1 Misgar Unit

This unit consists mostly of slates, with few intercalations of metacarbonate quartzite and black terrigenous slates, mostly exposed at the Northern part of the Project Area. In some areas, its thickness increases up to thousand meter. It is strongly folded with intensive development of slaty cleavage. The fold axes generally trend E-W up to the Khunjerab Pass, where they turn to NNW-SSE. The unit has low grade metamorphism indicated by chlorite, biotite, and muscovite. This unit is intruded by granitoide pluton in northern and eastern terrain having western extension up to Sost. This unit belongs to different stratigraphic formations of Paleozoic age.

The southern boundary of Misgar Unit is faulted with south vergent thrust plane, the northern fault stacking the Misgar Slate over Jurassic limestone and sandstones of Sost belt (Gaetani et al. 1990). Large recumbent folds present along the northern flank of the Chapursan valley suggest southward movement of Misgar Unit.

2.2.2 Sost Unit:

It consists of grey to dark grey slates, meta-limestone, and quartzite. At places, it has dolomitic patches (Gojal Formation). Some sandstone beds with slate intercalations overlain by argillaceous limestone (Gircha Formation) with some sandstone, siltstone, limestone and dolomites of Lupghar Formation, Panjshah Formation, Lashkargaz Formation, ranging in age from Middle to Late Permian.

It comprises of thick pile of folded and thrusted sheets forming in the whole antiformal stack, later disrupted by strike-slip faults. The unit is bounded by two major faults, the Upper Hunza Fault (Desio, 1979) to the south-east and the Northern Fault to the north. Complexity of the tectonic pattern often prevented the reconstruction of continuous stratigraphic successions, as in the Middle Late Jurassic sediments. Fold axes and fault striations along the main thrust surface generally indicate a N-S compression. The well-developed schistosity is defined by sericite, muscovite and fine grained biotite with occasional occurrence of epidote and chloritoid. This suggests that low grade condition of metamorphism with an important increase of temperature with respect to other thrust sheets of the Sost Unit. These shear zones are still poorly understood and may possibly be related to the eastward prosecution of Hunza Fault juxtaposing the Gircha Slates of Gojal Unit to analogues metasediments of Sost Unit. The stratigraphic succession present in the Sost Unit spans from Permian to Late Cretaceous.

2.2.3 Gojal Unit:

This tectonostratigraphic unit was defined by Gaetani et al. (1990) and includes the sediments lying between the KAB and UHF. It is composed of two units, a terrigenous unit (Passu Slates) below and a calcareous-dolomitic unit above. In the lower Shamshal valley, dolomitic marbles terminate along a subvertical NS trending fault while southward this unit is intruded by KAB.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Contact metapelites generally undeformed or poorly deformed intrusive that grades into biotite, muscovite, and andalusite. folds within the unit trend from NW-SE to NNW-SSE and are generally NE-facing. Thrust planes show the same trends and are NE-vergent, as in case of (UHF).

2.2.4 Karakorum Axial Batholith (KAB):

The KAB crops out along the southern part of the studied area, where two major plutonic complexes were recognized, the Hunza and Batura Units (Debon et al., 1987). The Hunza Unit consists in a huge plutonic unit extending for more than 250 km, made up of medium grained granodioritic in composition, locally recrystallized. They represent a calc-alkaline association. mafic enclaves of various sizes are abundant and a conspicuous network of Cenozoic leucocratic dykes is locally present.

The Batura Unit intrusive, spanning in age from Paleocene to Eocene, is mostly new, as well as the findings of plutonic bodies belonging to this unit in Upper Chapursan Valley. The Batura Unit includes two main intrusive; The Kuk and Sarbzea Pluton.

The Kuk Pluton consists of pinkish, undeformed and unfoliated granitoides of various grain sizes, locally with porphyritic, microgranular and rapakivi textures. The Sarbzea Pluton mainly differs from the Kuk Pluton by its very coarse to medium grained rocks, which were deformed at places.

2.2.5 Ganesh Formation:

This Formation consists of pelite-psammite turbidite unit and overlying calc-pelite marble unit and are intercalated with each other. These units are metamorphosed up to upper amphibolite facies and therefore have well developed sheets of amphibolite. The Formation has well developed ruby and spinal. Different mines are also established in this Unit as can be observed along road near Ganesh Bridge.

2.2.6 Hassanabad Granite:

It is well exposed in the Lower Hunza valley and consists mainly of lower s-type granitoid-migmatite complex with metasedimentary enclaves. These garnet-tourmaline bearing two mica granitoids and migmatites are well exposed in Hasanabad Nullah and in Hunza valley along Hunza River.

2.2.7 Chalt Formation:

It consists of dark grey quartz biotite schist with subordinate quartz, marble and conglomerate. It is exposed along overturned anticline and faulted against Dumordo Formation. Permo-Carboniferous age is assigned to this Formation.

2.3 REGIONAL TECTONICS

Before the Northward flight of the Indian Plate, small continental pieces (Cimmerids, i,e. Karakorum Block, Helmad Block, Hasha Block etc) were broken up from the Northern edge of

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Gondwana Land and welded with the southern edge of Eurasian Plate, consuming the old Tethey and opening the Neo Tethey, (Tapponnier, 1975, 1977; Molnar, 1977a).

In general, due to the subduction of the oceanic part of the Indian Plate beneath the Eurasian Plate, the Island Arc emerged in Middle Cretaceous age. The Arc Complex consists of calc-alkaline plutonic rocks mainly mafic in nature. The presence of blue schist metamorphism in Swat and Shangla Area indicates the trench environment.

The collision of the Indian and Asian Plates has been described as a “head on” north-south collision (Shackleton and Ries, 1984). This is generally accepted by many workers to have occurred in Eocene times (55-40Ma) (Powell, 1979; Klootwijk et al, 1979; Dewery et al, 1988; Treloar and Coward, 1991; Serrle et al, 1987, 1988). The terminal collision between Indian and Asian Plates is suggested to have occurred between 45-40 Ma (Molnar and Tapponnier, 1975; Klootwijk et al, 1985). It is generally agreed, however, that by 55 Ma, the Kohistan Island Arc was already sutured to the Asian Plate, probably since the Late Cretaceous, forming the MKT zone. This is confirmed by the presence of 85-80 Ma thermal event at this time (Treloar and Rex, 1990).

The rocks of Shyok Suture Zone (SSZ) are interpreted to represent the tectonised remainder of a marginal basin. The closure of the marginal basin occurred at the Eocene-Oligocene time boundary, and crustal shortening was responsible for generation of Neogene 2-mica granites of the KAB and regional metamorphism of the Pangong Tso Group (V.C Thakur, D.K. Misra, 2007).

The collision between the Indian Plate and Kohistan Island Arc is recognized as when the Tethyan Ocean disappeared and the continental masses docked. Following features recognize the main arguments for the Eocene age of collision: -

- Sediments deposited on the northern margin of the Indian Plate being of Eocene age.
- Subduction of the oceanic crust stopping, as recognized by the end of calc-alkaline magnetism north of the Indus Suture.
- The Blue schist facies are not developed along MKT zone showing the collisional belt.
- Slowing down of the Indian Plate motion, as recognized by magnetic anomalies.
- After collision, continued suturing occurred, associated with a 35˚ anticlockwise rotation of the Indian Plate relative to Eurasia. As a result of collision, mighty mountain ranges of Himalayas were developed having Island Arc Sequence in the north.

There are some topographic observations about the Himalayas that were immediately noticeable:

- The general curvature of the mountain chain.
- The mass of high land behind the mountain belt (Tibetan Plateau)
- The lineament of the high peaks confined in a rather smaller area.

This seemingly simplified chain becomes very disturbed, with a complete loss of these features in the Northern Himalaya. The general curving of the Higher Himalayan peaks and the suture

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

around angles of some 180˚ is related to the structural anomalies that are present in Northwestern Himalaya: i.e. the syntaxes (Nanga Parbat Syntaxis, Hazara-Kashmir Syntaxis etc). These are absent in Central Himalaya. This shows that the collision between two plates is not a simpler phenomenon but there was a much greater extent of deformation to which the collision was accommodated. The accommodation was not constant, but suggested to be partitioned with different mechanisms occurring in different places of the orogenic belt.

Anticlock wise rotation of Mega Lhasa followed the Late Triassic docking of the Iranian Spur, using the later as pivot. The rotation was completed during the Middle Jurassic, when SE Pamir, Shaksgam and Karakorum joined the Qiangtang, more closely assembling Mega Lhasa as it approached the Asian margin (Maurizio, Gaetani, 2007). The Karakorum Block (KB) bounded in the east by Karakorum Fault, in the north by Rushan- Pshart Suture, in the west by Herat Fault and in south by MKT.

Structurally the KB is characterized by broad asymmetrical to tight, isoclinal folds which are commonly imbricated. A number of large regional scale thrust faults, e.g. the Tirchmir Fault, Reshun Fault, Baltit Fault, Upper Hunza Fault, Chapursan Fault and the MKT extends for a distance up to 100 km or more. The KB has undergone multiple deformation since the Cambrian. Parts of the KB have undergone at least four more deformations since the Kohistan-Karakorum collision from Paleocene to Pliocene.

After the collision, due to further Northward subduction of the Indian Plate, still active 4cm/yr, the stresses were accommodated by the imbricate thrust faults from North to South (Treloar et al, 1989). The collisional history along with metamorphic events trapped many clues between these fault systems. These are very useful to delineate the historic events and to unrivaled the movement of Indian Plate, collisional environment and modern deformational style.

2.4 REGIONAL FAULTS

The major regional faults of the region include, from north to south, the Main Karakorum Thrust (MKT), Main Mantle Thrust (MMT), Panjal Thrust (PT), Main Central Thrust (MCT), Main Boundary Thrust (MBT), Kashmir Boundary Thrust (KBT)/ Himalayan Frontal Thrust (HFT) and Salt Range Thrust (SRT) **(DWG No: AFS-GE-292)**.

Along with these regional faults, many local faults were developed to accommodate the regional stresses, these may be thrust fault or strike slip fault in nature. In most of the area many small scale strike slip faults are associated with the thrust faults to accommodate the deformation.

The general trend of these faults excluding MKT is predominantly east-west with change in trend due to syntaxial bends. The general description of these major faults is as follows: -

2.4.1 Karakorum Fault (KF)

Dextral Strike Slip fault of about 800 km long bounds western Tibet. The KF represents a much younger terrane boundary, juxtaposing rocks of the Ladakh and Saltoro Blocks to those of Karakorum terrane. U-Pb zircon age of leuco-granites intrusion shows that it must therefore be

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

younger than 15 Ma old. Movement on the fault displaces the sequence approximately 200-250 km to South Eastern Tibet where the regional rock sequence can be regained (Burtman et al. 1963, Srimal 1983). It merges at the confluence defining a triple point and three blocks; the Ladakh Block to the south, Saltoro Block to the northwest, and the K KB to the northeast.

A number of teleseismic events have occurred along the fault. Interpretation of seismic data from 1975 Kinnaur earthquake confirms right-lateral strike slip motion on this fault. Three events were recorded from K KF Zone at the head of the Nubra Valley, since 1980, recorded by portable seismic stations, established by International Karakorum Project (IKP). It is seismically an active fault.

2.4.2 Upper Hunza Fault (UHF)

It is east west trending thrust fault that runs along the depression formed by the Chapursan and Upper Yarkhun Valleys (Zanchi 1973, Kazmi 1979b, Gaetani ey al. 1995). In this region it runs parallel to the northern margin of the KAB. Southeast of morkun (Upper Hunza) three teleseismic events of magnitude 5-7 and focal depth of less than 50 km have been recorded. These epicenters form a cluster very close to the mapped trace of the UHF. It means that the northern and western margin of the KAB is characterized by active zone of faulting along upper Hunza-Reshun Fault zone.

2.4.3 Main Karakorum Thrust (MKT)

The MKT is a low angle mega-shear with strike slip component, which on eastern side passes through Machlu in Hushe Valley, Shigar Valley, Zuhri Brook in Shyok Valley and Chalt in Hunza Valley extends westward through Ishkuman, Yasin and Shishi Valleys **(DWG No: AFS-GE-292)**. Its general trend swings between E and E-NE at low to medium dips towards the north. It is believed that this fault is seismically active.

2.4.4 Main Mantle Thrust (MMT)

The MMT, which is aligned with the Nanga Parbat-Haramosh tectonic line on east, span an area of about 400 km through Diamir, Kohistan, Swat, Dir and Banjaur, before entering Afghanistan **(DWG No: AFS-GE-292).** The general trend of MMT is NE-SW. It is located along the contact of the mafic/calc-alkaline meta-igneous rocks and the meta-sediments belonging to the Indo-Pakistan Continental Mass. Along this megashear near Jijal Village on Indus River (right bank), the igneous rocks have overthrusted the meta-sediments to the south over a 10-15 km wide zone. The thrust also manifests as the broad high topography of Kohistan relative to the Hazara adjacent to the south. In addition, numerous auxiliary fractures are developed and across the thrust frequent brecciation and mylonitization are also present along the contact. It is seismically active fault.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3 SITE GEOLOGY

3.1 GENERAL

The Project Area lies in KB north of MKT. It is V-shape valley, originated by glacier and modified later on by Hunza River. It is stratigraphically as well as structurally controlled. The 2nd highest peak of the World K-2 lies in this range. The rock units comprise granitoides with pellite and psammite sequence ranging in age from Paleozoic to Cretaceous.

3.2 TECTONOSTRATIGRAPHIC MAP

The Neo-tectonic studies are carried out on enlarged SoP GT sheets at a scale of 1:15000 during site visit. Different tectonostratigraphic units have identified and marked on these sheets and presented as drawing **(DWG No: AFS-GE-318 to 320)** at a scale of 1:40,000. Different stratigraphic/geological units pragmatic have been marked and summarized below: -

3.2.1 Lithological Units

3.2.1.1 Soil Units

The recent deposits are the most widely spread soil units overlies the bed rocks. The slopes are covered with overburden having variable thickness. Terrace deposits comprise mixtures of clay, sandy silt, boulders and gravel in various proportions. These units are mostly present in Aliabad, Karimabad, Nagar and Gojal Areas.

The soil units present in the Project Area are described below: -

3.2.1.1.1 Angular Boulder Gravels with Sand and Appreciable Amount of Fines (ABGM)

Most of the slopes are covered by material comprise ABGM. This is colluvial material broken from the rock units, rolled down slope and settled at the foothill or along the slopes.

These deposits are mainly associated with crushed/brecciated rock units, originated/caused by brittle deformation due to faulting/shearing at both sides. It has been modified by erosion/weathering and accumulated as ABGM at foothills, forming active slides, at both side slopes.

3.2.1.1.2 Rounded Boulder Gravels with Sand and Appreciable Amount of Fines (RBGM)

River bed is mainly occupied by RBGM. Some exposure is also present at powerhouse site near old Chinese Camp, Helipad Area. Due to formation of lake, the bed of the river is mostly covered with silt and sand extends up to Shishkat Bridge.

3.2.1.1.3 Terrace Deposits

Terrace Deposits consist mainly of mixture of clay, silt, sand and gravels with occasional boulders. These are mostly developed in loose material (RBGM, ABGM, Morainic and Breccia) **(DWG No: AFS-GE-302,305 & 309)** in all villages, depending upon the availability of water.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The irrigation channels were built in such a way that the irrigation demands are meted out by glaciers. In Central Hunza (Hyderabad, Aliabad and Karimabad) water is mainly fed from Ultar and Hassanabad Glaciers. Similarly, from Gulmit and Passu Glaciers, the channels were constructed to fulfill requirement of irrigation water.

3.2.1.1.4 Morainic Deposits

It consists mainly of material ranging in size from large boulders to clay size particles, angular to sub-angular, elongated and have flat surface **(DWG No: AFS-GE-299 & 302)**. The direction of elongation indicates the route of advancement of glacier. These are well exposed throughout the valley.

3.2.1.2 Rock Units

The main rock units exposed in Project Area explored during neo-tectonic study are as follows:

- Granitic Gneiss
- Granodiorite
- Passu Slates
- Marbles

It is 70 to 120 km wide and 1400 km long structural zone comprises the Karakorum Crustal Plate(KCP) which is one of the fragment of Cimmerian Collage derived from Gondwana Land and accerated to Eurasia. The stratigraphic history of the Karakorum is similar as that of Himalaya up to Cretaceous. The Project Site mostly present in the KAB consists of Igneous and Metamorphic rocks.

The brief description of the rock units are given below;

3.2.1.2.1 Granitic Gneiss

It is light grey to grey in color on fresh surface and weathers to light brown, coarse to very coarse grained, moderately to highly jointed, highly sheared up to higher elevation due to faulting, sparsely to moderately weathered, moderately hard to hard. It has well developed foliation with trending value N61ºW and plunging value 79ºNE. It is exposed at the right as well as at the left bank of the Hunza River. Some shear zones are also present within the Unit **(DWG No: AFS-GE-293 & 312)**.

On the basis of petrographic analysis, it is evident that the major constituents' minerals present in Granitic Gneiss are quartz, oligoclase, biotite while amphibole, chlorite, muscovite, epidote, and tourmaline are present as minor constituent minerals. The high percentage of Quartz grains show strong strain extinction, indicating that this unit has Alkali Silica Reaction (ASR) potential. The rock may therefore not be used as a coarse aggregate with Ordinary Portland Cement (OPC) or High Alkali Cement. It may be used with low alkali cement, slag cement or cement with additives likes fly ash, pozzolan. Some chemical additives like lithium nitrate or silica fume can also be used to control this reaction. The Schmidt Hammer values ranges from

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

35 to **45 MPa** indicating that rock is moderately strong to very strong. But in some shear zone where rock is tectonized locally, this value reduces up to **18-20 MPa**.

3.2.1.2.2 Granodiorite

It is dark grey to blackish grey in color, weathers to brownish grey, medium to coarse grained, moderately weathered, moderately hard to hard, moderately jointed intruded by pegmatite and granitic gneiss. It is foliated with trend and plunge values of N60ºW/79ºNE. Further downstream, it becomes light grey to grey in color, coarse to very coarse grained. It is crushed, mylonized, and sheared at places. It is well exposed at both banks where it is intruded by many pegmatite dykes. Some shear zones are also present in this Unit.

On the basis of petrographic analysis, it is evident that Granodiorite is quite dominate in the Project Area. The major constituent's minerals present in this unit are plagioclase, k-feldspar, quartz, biotite, and amphibole while Iron, muscovite, chlorite, and epidote are minor constituents. The high percentage of quartz grains show strong strain extinction, indicating that this unit has ASR potential. The rock may therefore not be used as an aggregate with OPC or High Alkali Cement or it may be use with low alkali cement, slag cement or cement with additives like fly ash, pozzolan. Some chemical additives like lithium nitrate or silica fume can also be used to control this reaction.

3.2.1.2.3 Passu Slates

It is well exposed at both sides of Hunza River, in upstream reaches of Hussaini village. It has intrusive contact with granitic gneiss/granodiorite. It is dark grey to blackish grey in color and weathers to brownish grey, fine grained, moderately weathered, weak to moderately weak, moderately to highly jointed but sheared at places, caused by different faults passing through this Unit. In or near the area of Borith Lake this Unit is highly crushed and sheared.

It has transitional upper contact with marbles exposed further upstream. In Shamshal Nullah, the slate is highly crushed and disturbed. On the basis of brachiopods and bryozoans, present in this unit, Carboniferous to Permian age is assigned to this Unit.

3.2.1.2.4 Marble

It is well exposed along Hunza River, near Passu village in upstream area. It is massive and crystalline dolomite. It is off white to greyish white in color, weathers to yellowish brown color, fresh, moderately hard to hard, moderately to highly jointed but sheared at places, caused by different faults passing through this Unit. Brecciated marble is well exposed along the KKH before Passu Glacier. In or near the area of Borith Lake this Unit is highly crushed and sheared / brecciated.

The high peaks of well renowned Passu Cones are developed in this unit. It has transitional lower contact with Passu Slates, the transitional lithofacies of marly limestone has well preserved fusulinid assemblage. On the basis of fusilinid present in this Unit, Middle to Late Permian age is assigned to this Unit.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.3 GEOLOGICAL STRUCTURES

The Project Area tectonically lies in Karakorum Block. These units have undergone Karakorum as well as Himalayan Orogeny. The whole area has undergone/modified by two major fault systems MKT and Karakorum Strike slip fault. The MKT system which accommodated southward thrusting. Karakorum fault 800km long dextral strike-slip fault that bounds western Tibet, extending from the Pamirs to Gar Basin. As the Project Area has undergone multiple episodes of tectonics events, many regional as well as local faults and their splays have formed as discussed below.

3.3.1 Faults

Project Area has undergone compressional tectonic, resulted in release of energy forming thrust fault system with regional as well as local faults, bounded by MKT and Karakorum Strike Slip Fault (KSSF)**)**. These include:

- Batura Glacier- Hussaini Fault
- Borith Lake-Shamishal Nullah Fault
- Shishkat- Gulkin Glacier Fault
- Attabad -Hispar Valley Fault
- Central Hunza/Nagar- Chalt Fault
- Hassanabad Nullah Fault
- Hunza River-Nagar Fault

All these faults have been marked on the sheets and presented as **(DWG No: AFS-GE-318 to 320).** The dip and strike values of major faults have been plotted on the drawings.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4 NEOTECTONICS STUDIES

4.1 GENERAL

A large mass slided downward from right slope of Hunza River near Attabad village and chocked the River and destroy KKH for more than 2 km in January 2010. Chocking of Hunza River results in formation of a 25 km long lake up to Khyber village in Gojal Valley. Excavation work of channel through slided mass decreases down its level and span reduces upto Shishkat Bridge. Movement of huge mass downward is consequence of stress releases may have accompanied the direction of regional tectonic forces operating in this Region. To understand these regional forces and their effect and vulnerability of expected slope material to slide, Neo-tectonic study has been conducted.

This study covers the 40 km upstream and 50 km downstream of the Project Site along both banks of the Hunza River. Different features related to Neo-tectonics activity have been observed during site visit. In this study, particularly the focus has been to search the mode of deformation in recent deposits, along the both banks of river and its tributaries in nearby area.

The main objective of the Neo-tectonic study was to identify/observe the features of active tectonic events occurred in recent past about 0.1 Million years ago. There are many field observations regarding the Neo-tectonic activity. Some of the Neotectonics features/observation are given as under: -

- The tiltness in recent deposition, i.e. to study the slopes of gravels, clays, and sand layers w.r.t slope of the stream beds.
- Intersection of faults in recent deposits i.e. lacustrine deposits, terraces/ alluvial deposits or in any cultural features (houses, roads). The amount of displacement, Heave as well as Throw measurement, dip and strike of the fault.
- The presence of active slide zones.
- The displacement /uplift in fluvial as well as lacustrine deposits on each side of the lake/stream and magnitude of its displacement.
- Identify the zones of brittle as well as ductile deformation.
- To observe the movements along slicken sides / fault / joints blocks.
- The presence of escarpment slope along the planer area
- The presence of hanging valleys /cirques along main stream, in series and presence of waterfalls along it.
- Folding/bending in the recent deposits (alluvium, morainic, lacustrine).

A brief description of the right and left bank of the Hunza River has been described below: -

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.2 RIGHT BANK OF HUNZA RIVER:

Neo-tectonic features on the right bank of Hunza River in concomitant with different villages from upstream to downstream **(DWG No: AFS-GE-318 to 320)** are discussed below:-

4.2.1 Passu Village

Passu is one of the largest village in Gojal valley situated at the right bank of Hunza River along KKH about 35 km from Attabad Site. The great Passu Glacier, 56 km in length is present near the village. Many deformational evidences were observed in recent deposits along the road.

- 2-3 km Upstream of Passu Village

Co - ordinates

N 4038610.325 m

E 489292.583 m

El. 2470.03 m a s l

The coordinates have been measured by mobile topographer application.

A large deposit of RBGM material is present along the right side slope of the river along KKH. This material consists mostly of gravel, cobble, and pebbles with subordinate sandy material. Some inclinations in these deposits have been observed along roof and sole beds. This inclination varies from 15° to 35° layer-by-layer **(Photo 4-1).**

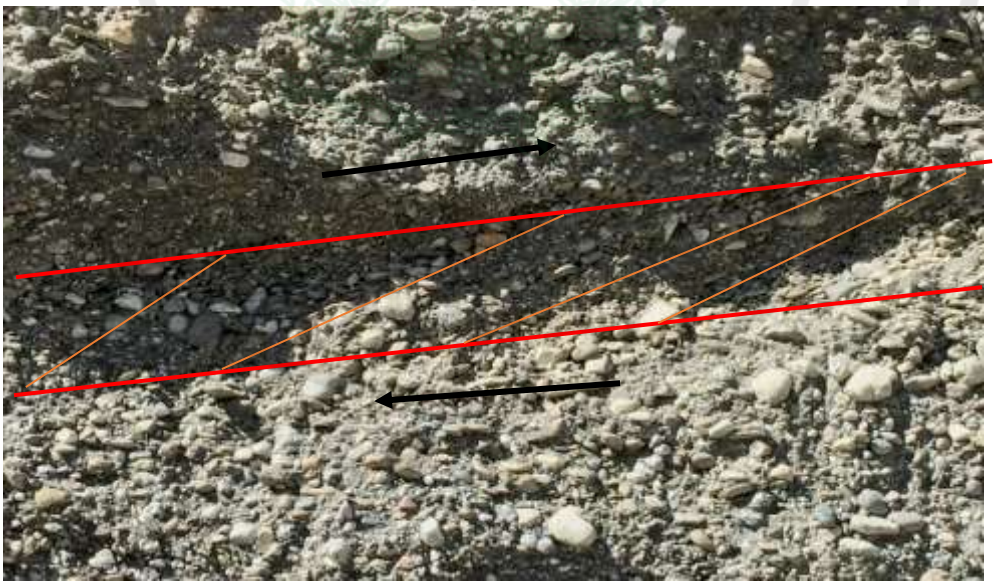

Photo 4-1 Inclined Gravel Layer Under Effect of Shearing

Some shearing effects have been chronicled along these planes in numerous layers. This shows that the area is tectonically active.

- In Passu Village

Co-ordinates

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

N 4039020.190 m

E 488598.996 m

El. 2521.0 m a s l

Further downstream, from previous station some clay deposits are reputable at right side slope in Passu village. Many Neo-tectonic features have been found in these deposits including jointing in recent clay deposits, folds, faults and associated structures, like tiltness in beddings.

Photo 4-2 Overall View of Clay Deposits and Inclination in Beds.

The clay deposit is overlain by morainic material of Batura Glacier. The clay deposits are tilted upward at an angle ranging from 10° - 15°. The area has undergone compressional regime, which uplifted the clay beds **(Photo 4-2)**.

Photo 4-3 Recumbent Fold Strata with Crenulation in Limbs in Clay Strata.

The clayey strata are folded with straight horizontal limbs and horizontal hingline. This shows that the horizontal compressional stress is applied on this material that turned this Unit into

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

folded strata **(Photo 4-3).** Many micro folds (crenulations) in both limbs of fold are present. The hinge area toward outer layers is pointed out; showing intense compressional stress has been applied to the strata.

Photo 4-4 Stylolite/Pressure Solutions in Clay Strata.

The strata show some stylolite structures that are formed by expulsion of water through pressure solutioning. Alignment of wavelength and geometry of hinge area indicates that the compressional stress has been applied horizontally **(Photo 4-4)**. This shows that the recent stresses are functioning in this area.

Many joints are developed in the clay beds showing that there is relative movement in blocks along the plane, which might be acted as micro faults **(Photo 4-5)**. The relative movement of hanging wall block moved down relative to the footwall block, signposted the development of normal fault.

Photo 4-5 Micro Faults in Clay Beds.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

At the same location there are cross cutting faults, dipping towards each other in clay beds. The block between two micro faults moved downward forming Graben structure while the block, that could not move formed Horst structure **(Photo 4-6)**.

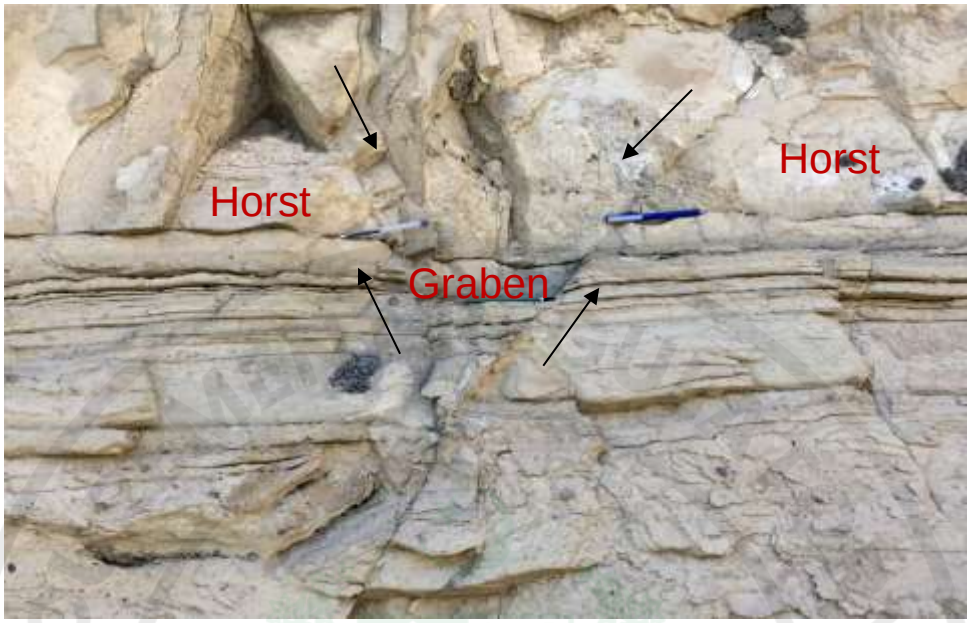

Photo 4-6 Horst and Graben Structure along Micro Fault in Clay Beds.

The formation of these structures in clay bed shows that there was relative movement along the micro faults in recent deposits.

The development of these normal faulting systems in such compressional regime indicates that these deposits have been under such environment where two thrust faults dipping toward each other. The up thrown block between these two faults undergone extensional regime where normal faults have been developed. This indicates that this area has been under active tectonics regime.

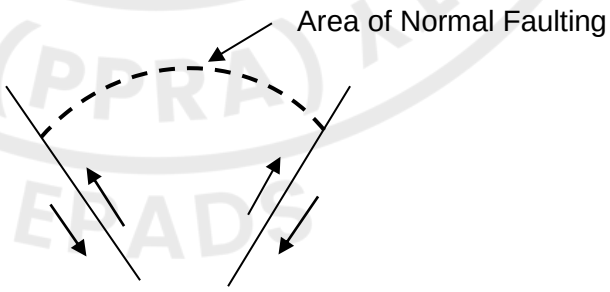

Figure 4:1 Development of Normal Faults under Compressional Regime.

Further, downstream, highly sheared marble and graphitic schist is exposed along the KKH. Highly sheared rock is cropped out up to high elevations and are accountable for the rolling down of boulders downward. Many active slides are instigating from this brecciated / sheared rock **(Photo 4-7)**, showing that this area has been under recent tectonic active stress.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-7 View of Active Slides in Passu Village.

In Passu village, there is a large shear zone along which the bedding joint have shear movement in marble. The shear zone is tilted inward **(Photo 4-8)**.

Photo 4-8 View of Bedding Joints along Shear Zone Passu Village.

This shear zone extends up to active slides and disappears. Highly sheared rock formed due to intersection of different faults are accountable for wide valley section.

4.2.2 Murradabad/Barut Village

Coordinates

N	4034396.199 m
E	491392.588 m
El.	2564.02 m a s l

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The Muradabad village has large cultivated terraces, irrigated by glacier water as well as by River. These terraces are developed on morainic material deposited by Passu Glacier.

In nearby Muradabad village just downstream of Passu village, a large morainic deposits of Passu Glacier is present along road. These morainic deposits are deformed due to release of compressional stress. The original deposited layers of boulder and gravels are allied and tilted up at an angle of 18° **(Photo 4-9)**.

Photo 4-9 View of Bedding Joints along Shear Zone Muradabad Village.

In this morainic deposit, folding in some clay layers are pragmatic. These folds are of small scale with minimum amplitude also the material is vertically jointed **(Photo 4-10)**. All these features indicate that the area is under regional compressional active stress.

Photo 4-10 View of Micro Folding in Clay Beds near Muradabad Village.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.2.3 Road section from Muradabad to Hussaini Village:

Co-ordinates

N 4033080.557m

E 489417.275m

El. 2656.69m a s l

Just upstream of Hussaini village a large mass of ABGM and brecciated rock is exposed along the road. It is present in the alignment of thrust fault where crushed marble is in contact with Passu Slates. The faulted contact between slate and marble is well exposed along road **(Photo 4-11)**.

Photo 4-11 View of Brecciated Rock Upstream of Hussaini Village.

In this area two faults are intersecting each other, one is striking N60°E and dipping 40°NW while other is striking NW and dipping NE **(DWG No: AFS-GE-318)**. Due to these faults discrete hillocks have formed with thin overburden overlain by fault breccia. At few feet away from breccia, a slided material consists of ABGM is present along road. Apparently this material seems to be stable but in excavated portion, this material is folded. Compressional forces are responsible for this deformation exposed at slope **(Photo 4-12)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-12 View of Folded ABGM Just Upstream of Passu Village.

Rock (Passu Slates) is locally folded, some shear joints along which the cleavage plane (originally bedding planes) across shear joint has different dip values. The overall strike of slates is NW and dipping in NE. but along this shear joint some movement took place and the value of dip changed from SW to NE **(Photo 4-13)**.

Photo 4-13 Change of Dip along Shear Joint.

Change of sense of dip along the shear joint shows that some shear forces have been active in the area. The development of such joints indicate the brittle deformation style.

4.2.4 At Hussaini Village

Coordinates

N 4031462.478 m

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

E 488964.085 m

El 2413.46 m a s l

At Hussaini village, thick deposit of RBGM is exposed at right bank of river, upon which terraces formed. The sand beds in this material are tilted at an angle of 25° **(Photo 4-14)**. Joints are developed in it shows that this deposit has undergone stress.

Photo 4-14 Inclination in Sand Beds in RBGM.

The gravels are compacted and exposed vertically owing to overburden pressure and breaks in blocky form. The gravels beds are tilted up from river at an angle ranges from 6° to 11° but at places it is inclined at an angle of 25° **(Photo 4-15)**.

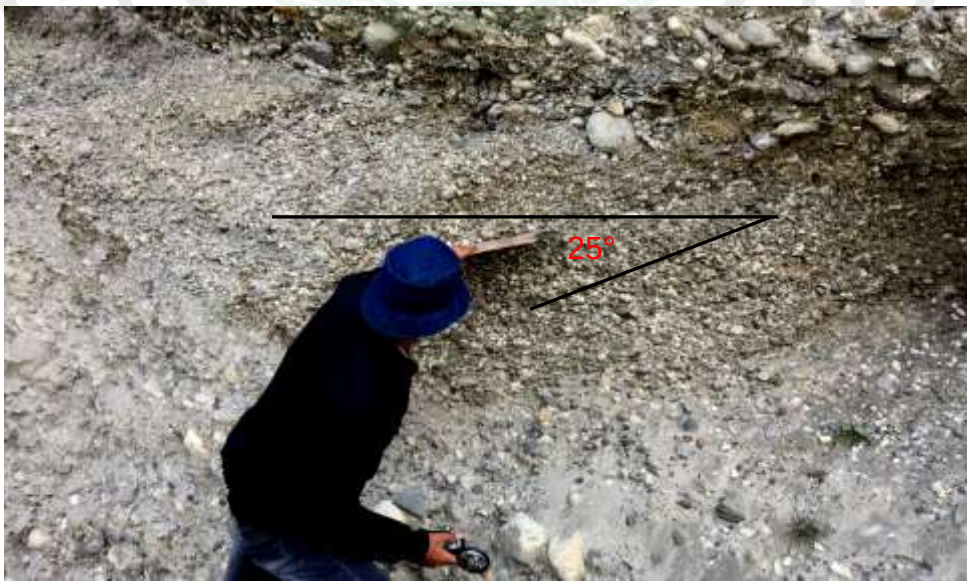

Photo 4-15 Inclination in RBGM.

This inclination in gravel bed indicates the effect of active shear forces operative on recent deposits and responsible for inclination in RBGM.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

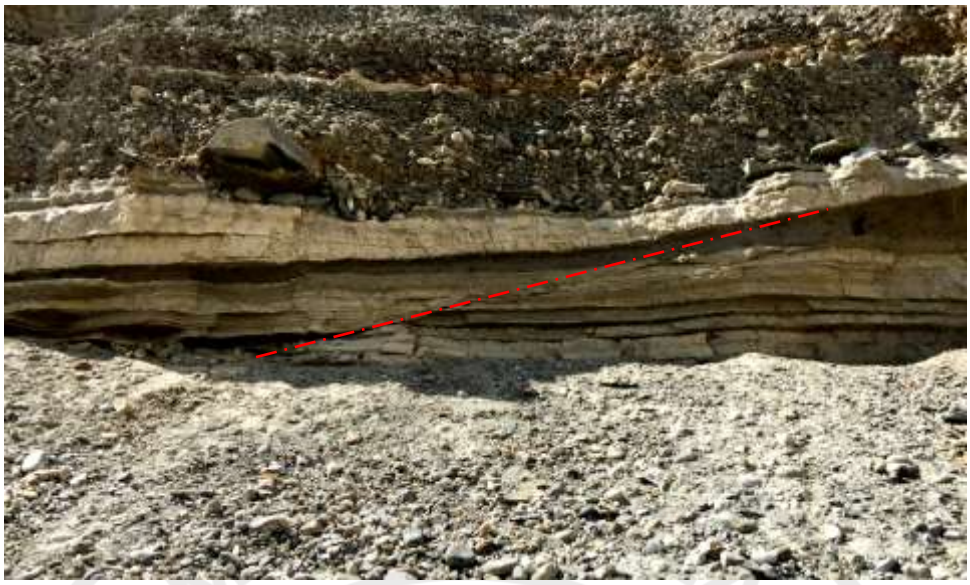

Photo 4-16 Micro Fault in Clay Deposit Overlain by RBGM.

A micro fault is observed in the clay deposits that cut the clays, perishes in RBGM, striking at N76°W and dipping 35°SW. The conglomeratic bed have pointed upward gravels, indicative of uplifting of deposit **(Photo 4-16)**.

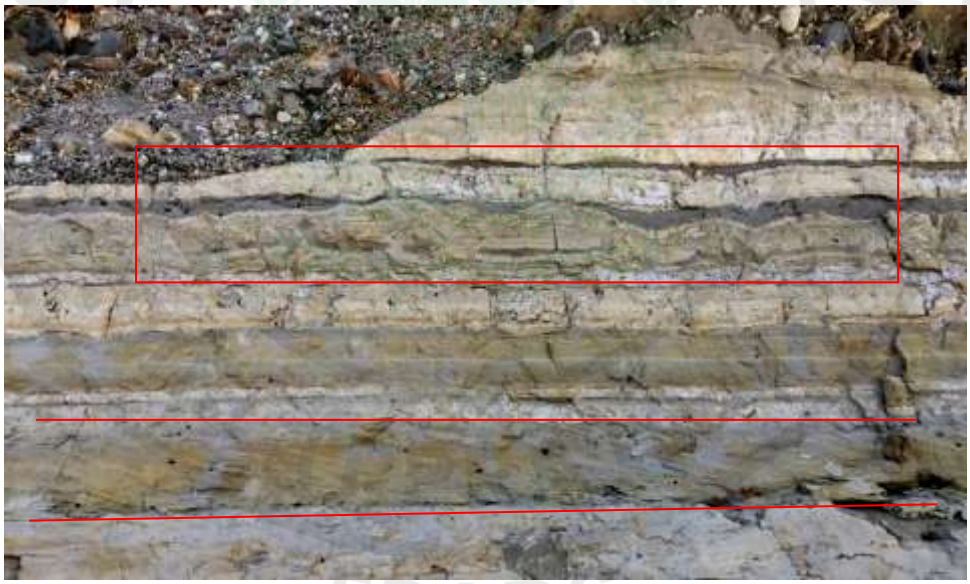

Photo 4-17 Micro Folding and Inclination in Clay Deposit Overlain by RBGM.

The highlighted lower portions in **(Photo 4-17)** indicate angularity in beds, tilted upward against the river flow direction. It shows that uplifting took place during deposition of these beds. Some compressional forces have been functioning which are accountable for evolution of micro folding in this strata. This intense deformation might be due to the compressional stresses operational in this area due to presence of active fault **(DWG No: AFS-GE-318)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.2.5 Way from Hussaini to Borith Lake:

Along the track from Hussaini to Borith Lake, sheared slates has intrusive contact with granitic gneiss. Some clay deposits are also present at higher elevations along road toward Borith Lake.

Photo 4-18 Contact of Granitic Gneiss and Passu Slates.

The slate is highly sheared/crushed and easily erodible. Micro folding and faulting along with jointing is observed in this deposited. The tiltness in beds is quite common **(Photo 4-18)**. These beds are tilted at an angle of 12° with horizontal surface.

Photo 4-19 Micro Faults in Clay Beds.

It is clear in above Photo that the sandy and clayey beds have movement along fracture planes. The hanging wall block move down relative to footwall forming normal faulting **(Photo 4-19)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-20 Fold in Clayey Silt along Trace to Borith Lake.

The folded strata in ABGM indicate that the area is under compression and stress are active in recent deposits **(Photo 4-20)**.

4.2.6 At Borith Lake:

Coordinates

N 4032452.941 m

E 487686.816 m

El. 2682.49 m a s l

At higher elevation from main KKH, a large lake of salty water is present. The alluvium material comprised of RBGM and sand has faulted contact with Passu Slate. Fault may be responsible for alluvium material to move up to the higher elevation. During the detailed study of area, different neo-tectonic features have been observed which are given below,

- Highly deformed sand and gravel beds.
- Tiltness in sand beds having inclination ranges from 15° to 25°.
- Cross bedding in sand beds.
- Folded strata.
- Pinching of sandy beds.
- Half fold.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-21 Highly Deformed Sand and RBGM.

The strata are highly disturbed and uplifted to high elevation by fault. Due to tectonic uplift different deformation phases have been observed in this deposit **(Photo 4-21)**. The deformational style shows that multidirectional deformational stresses are operational and responsible for deformation in recent deposits.

Sand beds in this area have tilted at an angle of 15° to 25°. The fault responsible for this is striking and dipping towards NE and NW respectively **(DWG No: AFS-GE-318).**

Photo 4-22 Inclination of RBGM and Sand Beds.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-23 Inward Inclination(curvature) of RBGM and Sand Beds.

Some sand beds have X-bedding which indicates that the direction of flow of water changes reasonably from time to time which is well preserved in strata at site **(Photo 4-21, 4-22, 4-23)**.

Photo 4-24 X-bedding and Pinching of Sand Beds.

Some beds are pinching against bedding planes indicate that the direction of river flow change abruptly due to operational stress **(Photo 4-24)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-25 Folding in RBGM and Sand Beds.

The above Photo indicates that the clay bed is folded showing the compressional environment. The tiltness of the bed is upward with lateral compression acting on the recently deposited strata.

It is observed during study that the lateral compression is operating in the Borith Lake area. The plastic behavior of clayey silt can be seen in folded strata where clayey silt is accumulated in hinge area of fold with increase in thickness of material (**Photo 4-25, 4-26)**.

Photo 4-26 Folding in RBGM and Sand Beds.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-27 Folding in RBGM and Sand Beds.

Many micro folds can be seen **(Photo 4-27)** showing that this very coarse grained gritty sand with silt intercalations is folded under lateral compression. The degree of deformation is quite high and the direction of compression changes from time to time as indicated by box fold with two hinge lines with one limb further folded as highlighted in rectangle.

Associated with this folding, some dislocation of silty beds are also observed along fracture surfaces representing compressional regime as hanging wall moves upwards relative to foot wall forming thrust fault **(Photo 4-28)**.

Photo 4-28 Micro Faulting in RBGM and Sand Beds.

These dislocations of beds, folding, tiltness, X-bedding indicate that the area is under active compressional stress.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

As moved further from Borith Lake toward Passu Glacier on kacha road, RBGM is present on both sides of the road. The schist present in rear area of Lake is quite sheared and the height of peaks reduces abruptly. Near the edge of Passu Glacier, the schist are in faulted contact with marble. The bedding planes of both blocks along the fault have different sense of dip **(DWG No: AFS-GE-318)**. The bedding of marble is trending N63°W and dipping at 39°NE while the schist is trending at N54°W and dipping at 78°SW.

Photo 4-29 Fault Breccia of Marble at High Elevation

Towards western slope of the Borith Lake, crushed marble is present at higher elevation. It is brecciated rock crushed by fault **(Photo 4-29)** and exposed as discrete units about 50 m above the water channel at slope. The coordinates of the breccia is

N 4032085.486m

E 487153.319m

El. 2771.47 m a s l

The depression had been originated by faults resulted to the formation of lake. The alignment of the fault is marked **(DWG No: AFS-GE-318)** along which no rock is present at track towards Hussaini village that confirms the presence of fault.

4.2.7 Just Downstream of Gulkin Glacier:

Coordinates

N 4029091.513m

E 488760.419m

El. 2445.0 m a s l

Near the Salvia Restaurant, just downstream of Gulkin Glacier along Hunza River, some alluvium material is present along the KKH. This alluvium is overlain by morainic deposit. Some tectonic features are well preserved showing movement in recent deposits along fractures. **(Photo 4-30)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-30 Micro Fault in Alluvial Gritty Sand.

Formation of jointing pattern in recent deposits, and movement along these fractures is clear indication of active tectonic stresses.

Photo 4-31 X-bedding in Sand.

Along with jointing, there is X-bedding in sand deposits. It indicates that the tectonic uplift might have taken place or the direction of flow change **(Photo 4-31)** responsible for X-cutting of sand beds.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-32 Folding in Clayey Silt with Pointed Hinge.

The clay layers in recent deposit are folded under lateral compressional force. The strata are disturbed and evident of Neo-tectonic activity **(Photo 4-32)**.

4.2.8 At Attabad Village:

A large slide moved downslope in January 4, 2010 forming a lake of about 25 km unto Khyber village near Batura Glacier. Pre-slided geological features indicate that Attabad village was situated on morainic material. The morainic material was underlain by granitic gneiss. The Attabad village was junction point of three faults **(DWG No: AFS-GE-319)** During surface geological mapping and neo-tectonic studies it is observed that fault “A” is along Hunza River, fault “D” has NE trending and another fault trending NW, merged at Attabad village **(Photo 4-33)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-33 View of Fault Alignment Crossing Hunza River near Attabad.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The rock is highly sheared, fractured and intensely jointed due to tectonic activity. Blocks of rock slided down mostly due to wedge failure. The shear strength of the rock reduces due to Neo-tectonic activity / movement along fault and failure occurs **(Photo 4-34)**.

Photo 4-34 View of Attabad Slide.

Firstly, some cracks appeared on the surface in cultivated terraces, with the passage of time the fractures grew and became wider and wider, accelerated by Hydrological conditions. As a result of operational neo-tectonic forces and hydrological condition, failure occurred in the form of enormous slide.

Mechanically sheared material under influence of tectonic forces disturbed and moved downslope by accumulating in riverbed and completely demolished about 2km of KKH.

The rock in downstream vicinity of slide is also sheared with many shear zones at right side while at left side in downstream areas, rock is brecciated due to fault **(DWG No: AFS-GE-319)** The Attabad slide is still active, as indicated by rolling down of material can be observed along this slide. It indicates that it is tectonically active area with some stresses releases along junction point/faults from time to time.

4.2.9 At Sarat Village:

Coordinates:

N	4018254.850 m
E	481549.816 m
El.	2371.35 m a s l

As a result of Salmanabad slide in the year 1858, a large lake developed in upstream reaches. The depositional clayey silt can be seen on both bank of Hunza River. Due to operational neo-tectonic forces, deformation including folding, jointing, and micro faulting have developed in these deposits.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Both vertical and oblique joints can be seen in clayey silt at right side near Sarat Suspension Bridge. The strike and dip values of vertical and oblique joints are N38°W/87°NE and N32°E/63°SE respectively **(Photo 4-35)**.

Photo 4-35 View of Vertical and Oblique Joints in Clayey Silt at Sarat Village.

Clayey silt beds are striking N 80°E and dipping 18°NW **(Photo 4-36)** at the left side of road leading to Sarat Village while at the right side of the road these beds have strike N 32°E and dipping 9°SE **(Photo 4-37)**.

Photo 4-36 Tiltness in Clayey Silt Beds, Left Side of Road at Sarat Village.

The strike of the beds is NE while the dip is in opposite direction, indicating that it forms some sort of antiform. Formation of antiform in recent deposits clearly indicates that lateral shear compressional forces are operational in this area.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-37 Tiltness in Clayey Silt Beds, Right Side of Road at Sarat Village.

Just downstream of Sarat Village near the suspension Bridge, fault breccia is exposed along the river showing the alignment of fault.

Photo 4-38 Folded and Sheared Clayey Silt at Sarat Village.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-39 Sheared and Smeared Clayey Silt at Sarat Village.

Photo 4-40 Fault Breccia just D/S of Suspension Bridge at Sarat Village.

Folding, jointing, smearing and shearing of clayey silt **(Photo 4-38, 4-39, 4-40)** deposit show some lateral stresses are actively operating in this area. The active slides and rolling down of brecciated material from this slope indicate that it is tectonically active area.

4.2.10 At Salmanabad Village:

Coordinates:

N	4018373.023 m
E	479430.485 m
El.	2661.0 m a s l

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

It is situated downstream of Sarat village and accessible by unmetaled road. The whole village is founded on fault breccia having many exposures of gaugic and brecciated materials. It is present along the road with alluvium material consist of sand and RBGM.

Photo 4-41 Fault Breccia along Road at Salmanabad Village.

The fault is striking N20°W and dipping at 58°SW with some parallel shear zones. Alluvium material RBGM and sand lifted upward along the fault B and fault C up to this elevation and are in contact with crushed marble **(DWG No: AFS-GE-319)**.

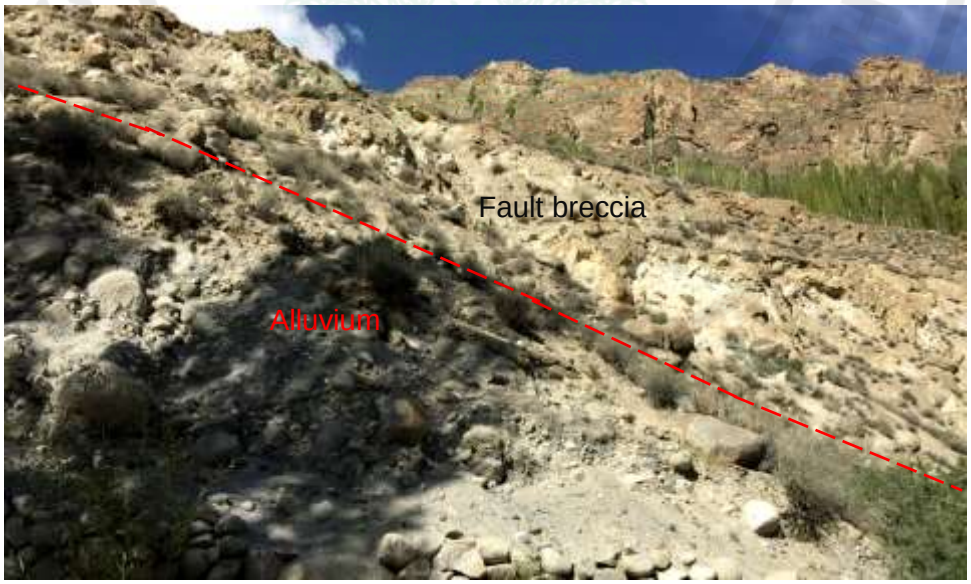

Photo 4-42 Faulted Contact of Breccia with Alluvium at Salmanabad Village.

As we move further up to higher elevations, the exposure of fault breccia and alluvium extend and well exposed up to elevation of 2704.02m **(Photo 4-41)**. Fault C is striking NW and dipping NE. Due to these two faults the whole rock beneath Salmanabad village is highly tectonized and crushed to the level of breccia and is well exposed along Hunza River **(Photo 4-42, 4-43).**

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-43 Fault Breccia beneath Salmanabad Village along Hunza River.

4.2.11 At Hassanabad Nullah:

Coordinates

N 4018015.083m

E 462346.127m

El. 2216.92 m a s l

At the nullah mouth, a shear zone trending NE and dipping NW sheared the rock and turned it into breccia. Micro folding, crenulation and isoclinal folding is quite common. The slopes are unstable with rolling down of boulders is quite common **(Photo 4-44)**.

Photo 4-44 Active Slides at Right Side Slope of Hassanabad Nullah.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The presence of active slides in the area is an indication of active tectonic forces.

Photo 4-45 Fault Breccia/Gauge along Road Just D/S of Murtazabad Village.

Just D/S of Hassanabad Nullah's confluence with Hunza River, along KKH, fault breccia of yellowish brown, reddish color, is exposed. A hot spring seepage is associated with this fault. A number of active slides have been activated along this fault. This fault extends further downstream and exposed in Nasirabad (Hindi) where a number of active slides are associated with this fault **(Photo 4-45)**.

4.2.12 At the Murtazabad- Shahyar Bridge:

Further downstream of Murtazabad toward Shahyar village, thick exposure of clayey silt is exposed along the road near the bridge. The beds are tilted inward, at an angle of 20° to 22° **(Photo 4.46)**.

Photo 4-46 Inward Tiltness in Clayey Silt Just D/S of Murtazabad Village.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Hummocky X-bedding is quite common in this deposit, formed under wave action with huge load under depth of water **(Photo 4.47)**.

Photo 4-47 Hummocky X-bedding in Clayey Silt near Murtazaba Village.

The whole deposit is jointed vertically along which falling of blocks is quite common.

4.3 LEFT BANK OF HUNZA RIVER

4.3.1 At confluence of Shamshal Nullah with Hunza River:

Coordinates:

N 4039351.149m

E 490847.707m

El. 2522.91 m a s l

Near the confluence of Shamshal Nullah at left bank, morainic deposit having clay layers is exposed. It is jointed and range from clay to morainic material **(Photo 4-48)**.

Along Upstream course in Shamshal Nullah, the Geological conditions become worst. The left side of nullah is highly crushed responsible to generate many active slides, associated with active fault system. Passu Slate is highly crushed/tectonized, sheared and folded, near the confluence of Shamshal Nullah with Hunza River **(Photo 4-50)**.

At right bank of Shamshal Nullah, many active slides originating at higher elevation from Passu Cones deposited their load in foothills. The rocks are highly crushed up to higher elevations at both sides of Shamshal Nullah due to intersection of two faults, one is running from Borith Lake while other is running from Batura Glacier **(DWG No: AFS-GE-318)**

Development of joints in morainic material, active slides, highly sheared and folded strata **(Photo 4-49)** show that the area is tectonically active.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-48 Jointing in Morainic Material, near Confluence of Shamshal Nullah with Hunza River.

Photo 4-49 View of Active Slides in Shamshal Nullah.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-50 View Of Folding, Crushed Rocks and Active Slides in Shamshal Nullah.

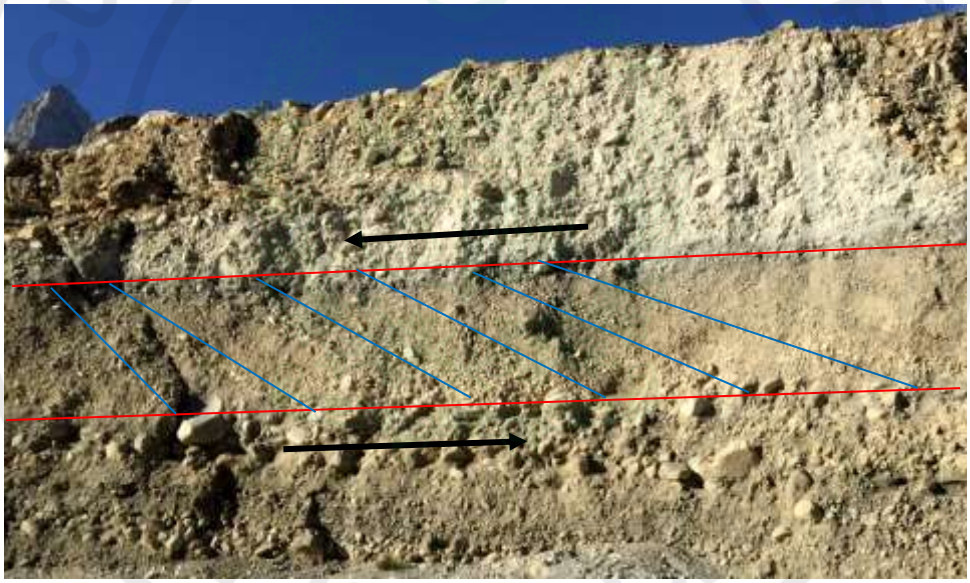

Photo 4-51 View of Inclined Gravel Bed Near Confluence of Hunza River and Shamshal Nullah.

Near the bridge at left bank of Hunza River, RBGM is exposed. The degree of inclination of these beds range from 15° to18° **(Photo 4-51)**. Some compressional shearing forces resulted inclination in these beds. Inclination along specific beds, packed by horizontal layers indicates that shearing force is operative along these layers.

4.3.2 In front of Gulmit and Gulkin Glacier:

Geological condition in this area is quite poor. A fault with strike and dip values N14°W and 42°NE respectively, **(DWG No: AFS-GE-318)**, crushed the rock into breccia. Whole rock unit disintegrated and accountable for rolling down of large boulders downwards forming active slides. The rolling down of rock pieces from higher elevation shows that some active tectonic forces are affecting on this slope and make it unstable **(Photo 4-52)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-52 View of Active Slides along Left Bank of Hunza River.

Further downstream, a fault passes through Shishkat village. The left side gradient becomes highly disturbed because of crushing of rock. Terraces of Shishkat village on breccia were formed by this fault.

4.3.3 In Perennial Nullah at the end of Tunnel 4:

Coordinates:

N 4019140.03m

E 489442.982m

El. 2482.0 m a s l

At the end of Tunnel 5, a perennial nullah is present. In this nullah about 600m upstream, fault breccia is exposed **(Photo 4-53)**. This nullah seems to be developed along large shear zone; originated from this fault, which is bounded by hard rocks on both sides. This fault / shear zone crushed the rock into breccia and responsible for the bending of Hunza River at 90°. This fault crosses the river and is responsible for active slide on right bank of river **(DWG No: AFS-GE-319)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-53 View Of Fault Breccia in Perennial Nullah.

4.3.4 Inside Tunnel 2

Many cracks/joint are going to develop in the concrete especially in crown area in Tunnel-2. The pattern of the cracks indicates stress release and shear oblique joints **(Photo 4-54)**.

Photo 4-54 View of Recently Generated Joints in Tunnel-2.

As far as geological conditions are concerned, this portion of tunnel in is under influence of two faults **(DWG No: AFS-GE-319)**. Rock is highly crushed, rolling down of boulders is quite common along these active faults. The active tectonic forces are responsible for the development of fractures in this terrain.

The same features can also be noted in concrete structure between Tunnel 2 and 3 **(Photo 4-55)** along KKH.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-55 View of Recently Generated Joints between Tunnel-2 & 3.

The concrete slab fractured between Tunnel 2 and 3. It is evident that some tectonic forces are recently active in this area.

4.3.5 Between Tunnel 1 and 2

The area between Tunnel 1 and 2 is highly sheared **(Photo 4-56)** due to influence of fault with strike and dip values of N52°W and 50°NE. This fault is a splay of Hunza Fault **(DWG No: AFS-GE-319).**

Photo 4-56 View of Fault Breccia between Tunnel-2 & 3.

The rock is highly tectonized / brecciated. The extension of this fault is upto old KKH route and exposed in rear of old Chinese camp. The breccia with some gaugic material indicates brittle shearing responsible for originating active slides. Along the alignment of fault, two springs are present in this area.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.3.6 Power House Area

In powerhouse area near helipad along old KKH, clayey silt is present where Chinese Camp was established. The clayey silt was deposited after river choking due to Salmanabad slide. Due to operational compressional stresses, some deformations including faulting, shearing, folding, and tiltness in clayey silt have been observed.

Photo 4-57 Micro Thrust Fault in Clayey Silt Beds near Helipad.

The relative movement of both blocks against fault plane indicates compressional environment, which moved the hanging wall block upward **(Photo 4-57)**.

Photo 4-58 Inclination in Clayey Silt near Sarat Village Bridge.

The clayey silt beds are well exposed at the left side of Hunza River near Sarat Bridge. The clayey silt beds are well jointed and tilted upward at an angle ranging from 10° to 15° **(Photo 4-58)**. The inclination of the beds are in recent soil is indicative of active tectonic forces.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Near old Chinese Camp, at powerhouse area, the clayey silt is folded **(Photo 4-59)**. Folding in recently deposited clayey silt might have resulted of slipping along fault plane under regional compressional shear forces which resulted in the formation of folding and faulting.

Photo 4-59 Folding in Clayey Silt near Helipad/Power House Area.

Near the SCO building, along old KKH, near Tunnel-1, some cracks are going to develop in recently deposited material. The development of joints is mostly parallel in nature but occasional cross cutting joints also present **(Photo 4-60)**.

Photo 4-60 Development of Parallel Joints near SCO Building.

4.3.7 In front of Salmanabad and Ahmadabad Village:

Along the KKH, opposite to the Salmanabad and Ahmadabad, the slope is highly disturbed. A regional fault striking NE and dipping SE is running through this area. The fault and its splays crushed the rock outcrop. The area in front of Salmanabad is highly tectonized with a number of

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

active slides **(DWG No: AFS-GE-319)**. The breccia consists of rock pieces with gaugic material **(Photo 4-61)**.

Photo 4-61 View of Active Slides in front of Salmanabad.

While the area in front of Ahmadabad also consists of brecciated rock but slopes are stable **(Photo 4-62)**. The drainage pattern is dendritic in higher elevation changes into parallel near the road which indicates that sheared rock is present up to higher elevations.

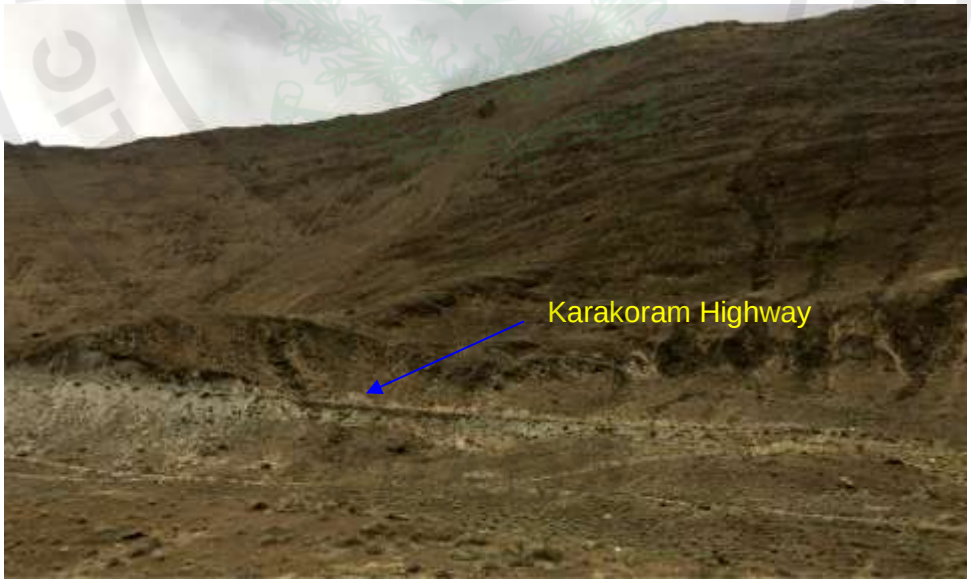

Photo 4-62 View of Stable Slide in front of Ahmadabad.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-63 Panoramic View of Slope in front of Salmanabad and Ahmadabad Village

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The rock at the slope in front of Ahmadbad along KKH is crushed, brecciated but there is no evidence of active tectonic forces in this section. Thin overburden ranging in thickness from 2 to 5 m underlain by sheared/ crushed rock, covers the slope. It suggests that the splay passing though this area is not active **(Photo 4-63)**. However, the topographic features, drainage pattern, left side slope of mountain terrain, and presence of brecciated rock in non-perennial nullah are clear cut indicator of fault system present in this area.

4.3.8 Upstream of Ganesh Bridge:

Coordinates:

N	4018284.00m
E	473257.772
El.	2211.23m a s l

Just upstream of the Ganesh Bridge, a large deposit of clayey silt is present at left bank of river underlain by thick RBGM material. It is observed that this material is under the influence of tectonic forces. The clayey silt beds have sheared zone striking at N72°E and dipping 88° SE **(Photo 4-64)**.

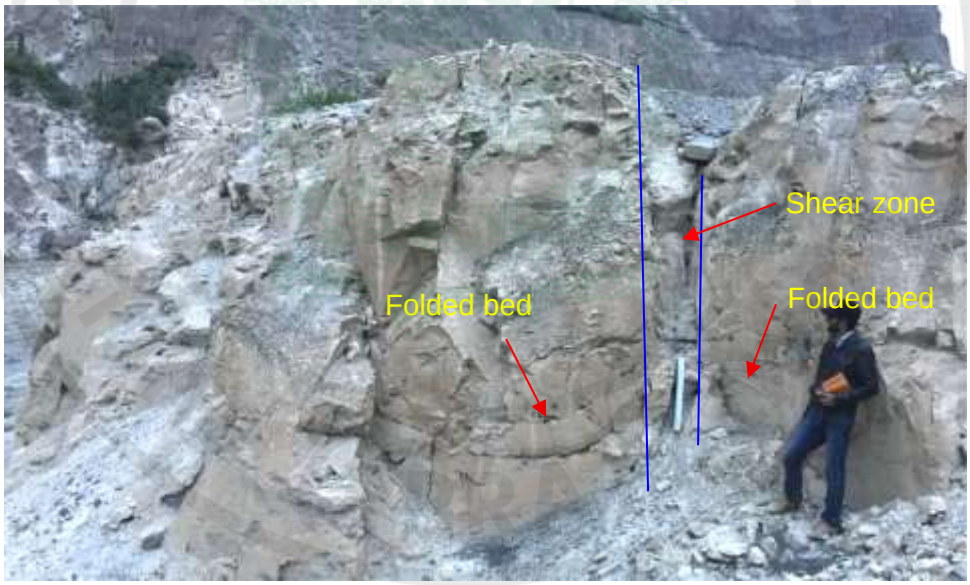

Photo 4-64 View of Shear Zone and Folding in Clayey Silt.

The clayey silt beds are folded across this shear zone. Associated with this, clayey silt beds have displaced along fracture plane with displacement of 12cm **(Photo 4-65)**. Beds of clayey silt are tilted up at an angle ranging from 6° to 20° in upstream direction. These features indicate that this area is under influence of active tectonic forces.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-65 View of Micro Fault and Displacement of Blocks.

4.3.9 Near Kiln Upstream of Ganesh Bridge:

Coordinates

N 4018656.896m

E 471625.513m

El. 2185.0 m a s l

It is observing near Kiln that gravels, cobbles, and pebble in RBGM are tilted upward against the flow of Hunza River **(Photo 4-66)**. The inclination is 20° in RBGM and 18° in clayey silt beds.

Photo 4-66 Inclination in Gravel Bed near Kiln

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Similarly, along KKH, tiltness in ABGM and clayey silt beds is observed ranging from 5° to 10° **(Photo 4-67).**

Photo 4-67 Inclination in ABGM and Clayey Silt Bed along KKH.

It is observed during site visit that some longitudinal joints are developed in morainic / slided mass, laying over the rock. It is evident that trend and sense of force is same as that of underlying rock **(Photo 4-68)**.

Photo 4-68 Development of Jointing in ABGM Underlain by Rock along KKH.

4.3.10 At Ganesh Bridge

The rock (Granotoide) with coarse to very coarse grained interbed marble is well exposed at left side along KKH. The rock is highly foliated and can split easily along this weak plane. Low amplitude folds with longitudinal joints are well developed. Some open joints intersecting with oblique joints might have caused the rock fall **(Photo 4.69)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-69 Development of Longitudinal Joints in Rock along KKH.

The development of longitudinal joints in rock outcrop and falling of blocks show that some recent forces are operational in this area.

4.3.11 Just downstream of Ganesh Bridge:

Coordinates

N 4018200.432 m

E 470296.520 m

El. 2104.05 m a s l

At the confluence of Hispar River with Hunza River, there is thick deposit of RBGM present up to high elevations. The RBGM has subordinate sand beds. This recently deposited strata are quite disturbed. Many tectonic features have developed in this deposit including: -

- Inclination
- Folding
- Crenulation
- Folds with bulbus hing

Just upstream the confluence along Hispar River, thick RBGM is present along road. The material is under influence of intense deformation. The RBGM is tilted at an angle of 45° to 50° **(Photo 4-70)**. It is tilted upstream and extends up to higher elevations.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-70 Inclination in RBGM at Left Bank of Hispar River.

The compressional forces responsible for deformation are associated with NE striking thrust faults passing near the area. Folding with bulbus hinge, box fold, recumbent fold are well exposed near the confluence **(Photo 4-71)**.

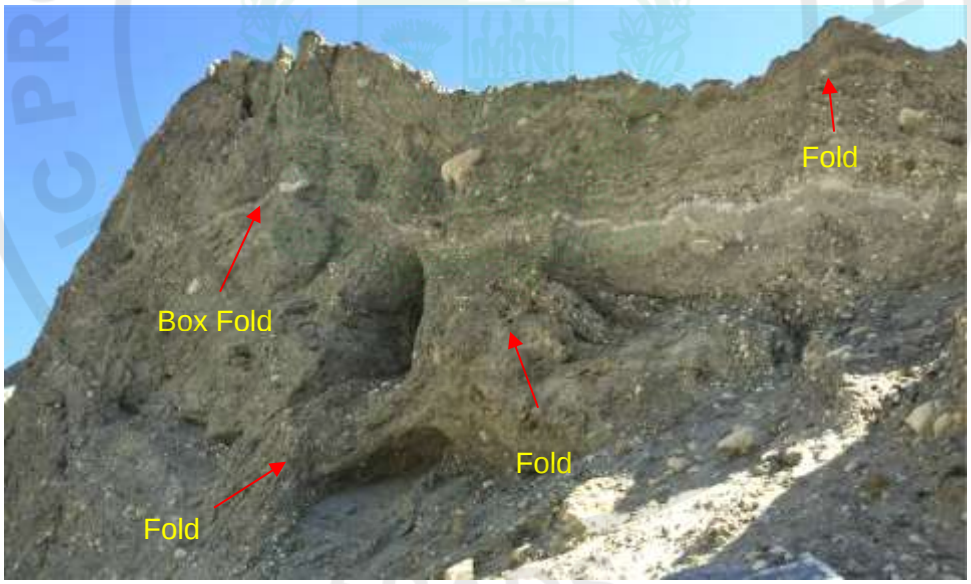

Photo 4-71 Folding in RBGM along Hispar River.

Due to intense compressional force, some beds are folded with inclined hinge. Both limbs are dipping in same direction **(Photo 4-72)**. The presence of folds in recent deposit indicates that, compressional force deformed this strata. The alignment of all folds is not uniform, indicates that multidirectional stress are applied in different episodes.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-72 Inclined Isoclinal Fold In RBGM along Hispar River.

4.3.12 In Hispar Valley:

Coordinates

N 4017966.628m

E 470008.848m

El. 2107.24m a s l

Overall the geological conditions in Hispar Nullah are quite disturbed. The right side slope is mostly brecciated and consists of ABGM with RBGM. Gravel with sand beds is well exposed at the right side of Hispar Nullah are tilted up at an angle ranging from 22° to 30° **(Photo 4-73)**.

Photo 4-73 Inclination in Gravel Beds Tilted Upstream along Hispar River.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Major faults with their splays disturbed the area and extend further westward into Nagar valley. The whole valley up to Hoper Glacier is highly brecciated with some exposure of competent rocks.

Photo 4-74 Inclination in Gravel Bed Tilted Upstream along Hispar River.

It is clear in **(Photo 4-74)** that the sand layer is folded with inclined gravel beds with the formation of box fold, flat lower area with nearly straight limbs. These features were resulted from compressional forces associated with thrust fault.

About 3 km from confluence of Hispar and Hunza Rivers, the gravel beds are tilted at low angle ranging from 6° to 10°. The beds are tilted upstream, indicating upward movement of recent gravels **(Photo 4-75)**.

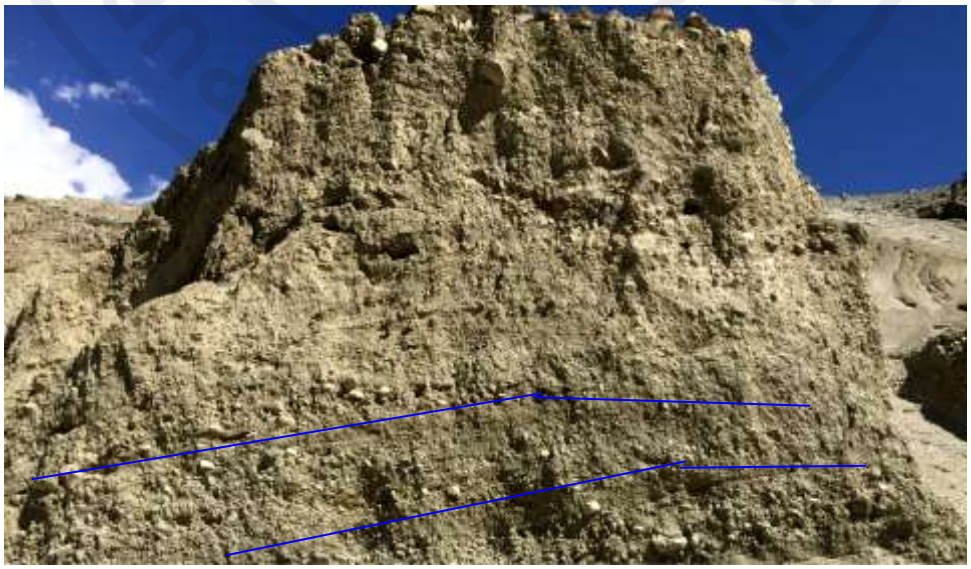

Photo 4-75 Inclination in Gravel Beds Tilted Upstream along Hispar River.

At Tukurkhai village, the fault breccia is exposed o both sides of a perennial nullah striking NE and dipping SE **(Photo 4-76)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-76 Fault Breccia at Tukurkhai Village on Left Bank of Hispar River.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The rock is highly crushed and slopes are unstable. The nullah is developed along the extension of fault and well exposed along the road. All the terraces are developed upon the brecciated rock.

4.3.13 At Nagar Valley

The whole Nagar valley including Sumayar, Shahyar, and Hakuchar villages are situated on fault alignment **(DWG No: AFS-GE-320).** All the terraces were developed on fault breccia. Rocks are sheared and disturbed in this area **(Photo 4-77)**.

Photo 4-77 Fault Breccia near Hakuchar Village with Active Slides.

The slides are active, rolling down of material from crushed rock is quite common. It is present upto higher elevation and is responsible for the choking of Hunza River in the past. Due to development of lake, clayey silt was deposited and exposed along the both sides of river. The presence of active slides indicates that, fault is active in this area.

4.3.14 At Murtazabad - Shahyar Road

Coordinates:

N	4016299.113m
E	465418.47m
El.	2095m a s l

Just crossing the Murtazabad to Shahyar Bridge, a thick alluvial deposit consists of gravels, cobbles, pebbles interbedded with silty sand is exposed. This material moved upward against fault plane and formed fault bend fold **(Photo 4-78)**.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-78 Inclination in Clayey Silt and Gravels.

The beds are tilted at an angle of 22° to 30°. Many micro faults in sand beds have been observed in hinge area of the fold. The ramp and flat geometry have NE strike with dip in SE direction. **(Photo 4-79)**.

Photo 4-79 Ramp and Flat Geometry along Fault.

Some micro faults have been observed in this alluvium. Step faulting on micro level is well preserved in sandy material **(Photo 4-80)**. This alluvium is overlain by morainic material; same joint pattern is going to be developed in it. Some open joints ranging from 10cm to 150cm have been observed there. All these features indicate that the tectonic forces are active in this area.

At the left side slope of Hunza River, crushed rock with major constituents of gaugic material is exposed. The slopes are unstable due to active fault movement **(Photo 4-83)**. Well-developed garnets are present in granitic gneiss metamorphosed upto schistose grade.

Photo 4-83 Highly Crushed Rock in Maicher Village along Road.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Photo 4-84 Panoramic View of Crushed Rock and Drainage Pattern at Miachar Village.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

A fault striking N45°E and Dipping 40°SE is running through Maichar village. Intersection of 3 to 4 faults, (coming from Central Hunza and Hassanabad Nullah), the rock is highly crushed and disturbed **(DWG No: AFS-GE-320).** Due to which, dendritic drainage pattern is well developed along the left side slope of the River. Fault breccia is well exposed along the road section.

Maichar village is developed on highly crushed rock with dominant gaugic material. The cultivated terraces are well developed on this material. Due to seepage of water and some tectonic movement along the faults, a large fracture seems to be opened along the slope, in back side of Maichar village. It is quite hazardous in the near future. The whole slope may become unstable and slide down.

5 CONCLUSIONS OF NEOTECTONICS STUDY

- The Project Area lies in KB, where Igneous, metamorphic and sedimentary rocks are exposed.
- It is a V-shaped valley originated by glacial activity, modified by river and controlled structurally by tectonic activity. The MKT and its splays at the Western side while Karakorum Fault and its splays at the Eastern side are the factor controlling the valley's morphology.
- The Project Area lies in the vicinity of active tectonic zone, responsible for the massive landslide at Attabad village. It chocked the Hunza River and creates about 25 km long lake up to Khyber village. After the excavation of spillway, the lake length reduces to 15 km.
- The area under study shows that the active tectonic forces are operational in this area; the sliding of huge rock mass is one of the major evidence of neo-tectonic activity.
- During the current study about 40 km upstream and 50 km downstream area have been investigated. There are many deformational features observed in the recent deposit. Many evidences of chocking of Hunza River have been found in deposited clayey silt at number of locations.
- During site visit many deformation phases have been observed in the recent deposits including, faulting, folding (fault bend fold, chevron fold, ramp and flat geometry), jointing, tiltness in sand and gravels, step faulting, cross bedding etc., throughout the stretch. These structural features are associated with different thrust fault systems under compressional regime.
- The whole area suffers under tectonic forces that might have contributed some seismic events in this area. During the study fault geometry, nature of fault, and slope disturbed due to these faults have been studied to incorporate in Seismic Hazard Analysis Report.

6 SEISMIC HAZARD ASSESSMENT

6.1 INTRODUCTION

Hydro Planning Organization (HPO), Pakistan Water and Power Development Authority (WAPDA) have undertaken the Feasibility Study of ALHPP in GB.

The proposed Project is located on Hunza River about 20 km upstream of Aliabad village about 130 km from Gilgit and about 750 km from Islamabad. Project Area is under the administrative control of GB. Hunza River is one of tributaries of the Indus River. The location coordinates of newly proposed inlet portal of diversion tunnel has been used as tentative reference coordinates for seismic hazard analysis of the Project and the coordinates are given below:

Latitude 36.313 N

Longitude 74.861 E

As the earthquakes hazard to water retaining structures is very important consideration in the design of civil structures, it requires careful analysis for selecting seismic design parameters for water retaining structures. The goal of the earthquakes-resistant design is to produce a structure that can withstand a certain level of shaking without excessive damages to the water retaining structures. Thus, the specification of design ground motion parameters is one of the most important difficult and most important problems in geotechnical earthquake engineering.

The Project Area lies in a unique geo-environment where all the typical hazards associated with mountainous areas exists including twin geo-hazards of earthquakes and landslides in addition to the possible danger of accidental and irregular melting of glacial waters resulting in huge sediments-loaded flooding potentials. Keeping all the triggering factors in view, care has been taken while selecting seismic design parameters for the updating Feasibility Study of the 54 MW ALHPP located on Hunza River. A composite map showing the location of the Project Area along with important physical features of the catchment areas and the area selected for seismicity analysis (Catalogue) is presented as Figure 6-1.

The Project Area lies in KB to the north of the MKT. Consequently, the MKT is the most prominent tectonic feature close to ALHPP, located at a distance of 32 km from the Project Site. Geological Map of Northern Pakistan and re-created Geological Map of Hunza Area were used in the softwares for seismic hazard analysis and these maps are presented as Figure 6-2.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

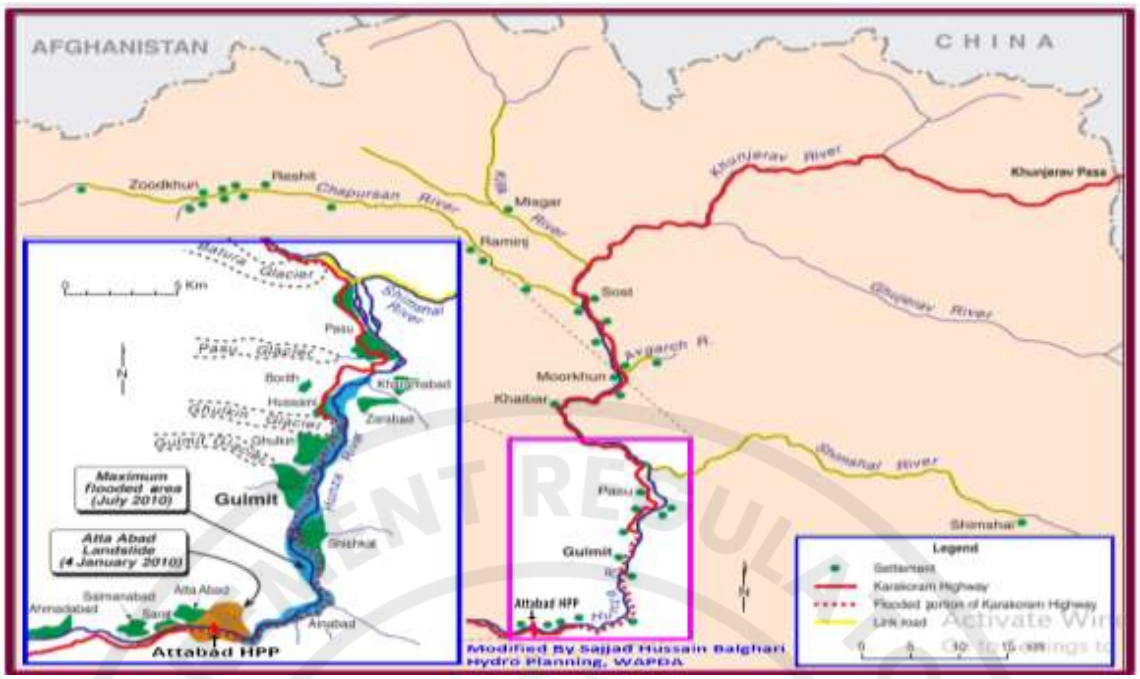

Figure 6-1 Composite Map Showing Location of ALHPP Site.

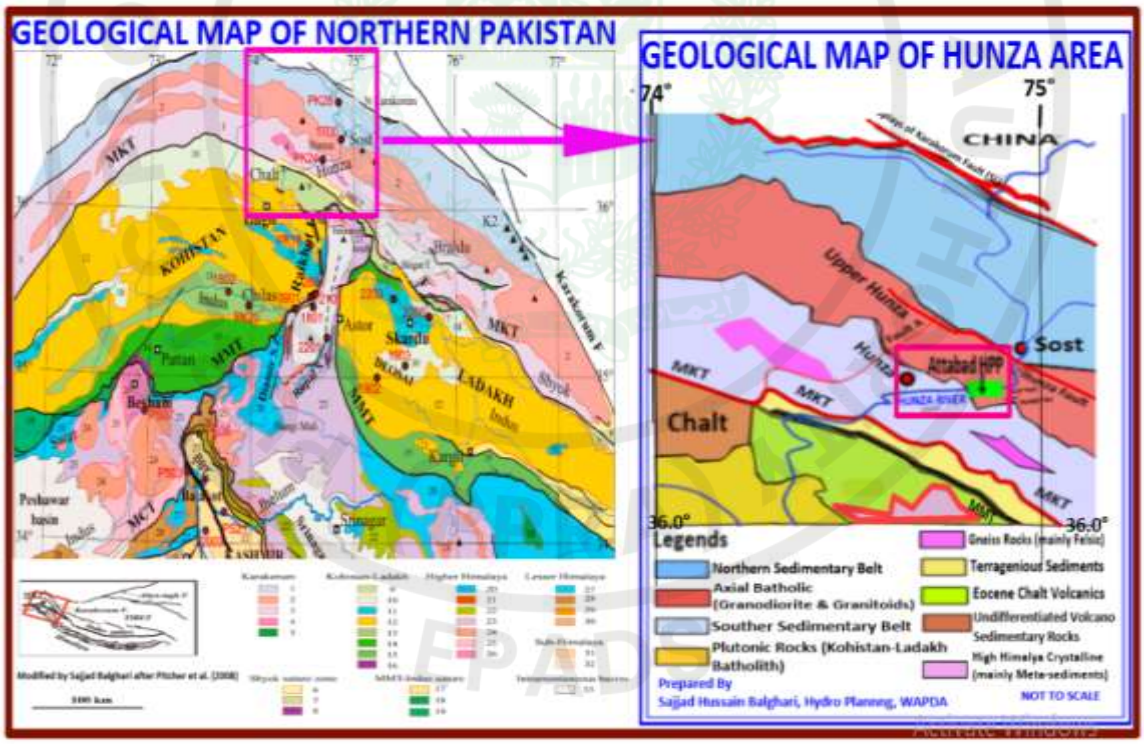

Figure 6-2 Geological Map of Northern Pakistan (Pecher et al. 2008) & Geological Map of Hunza.

Explanation to Legends (Left Map) i.e. Geological map of the Northern Pakistan modified by HPO, WAPDA after Pêcher et al. [2008]. Main tectonic boundaries: MKT, MMT, (Indus Suture Zone); STD, South Tibetan Detachment; MCT MBT; MFT, Main Frontal Thrust; BBT, Balakot-Bagh Thrust. Geological units at ALHPP are underlined: 1. Northern Sedimentary belt; 2, Axial Batholith, Granodiorites and other Granitoids; 3, Southern metamorphic belt; 4, Felsic gneiss; 5,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

greenstone complex, Paleozoic (Masherbrum complex). Unit B Shyok Suture Zone: reactivated along the MKT, 6, Predominantly terrigeneous formation; 7, Melange zone (volcanic); 8, Ultramafics (Shyok and Dobani-Dassu lineament). Unit C Kohistan: 9, Eocene Chalt Volcanics, Turmik volcanosediments; 10, Undifferentiated volcanosedimentary group; 11, Metasediments; 12, Plutonic rocks (Kohistan and Ladakh batholith); 13, Gabbronorites (Chilas Complex); 14, Southern amphibolites (Kohistan); 15, Dras volcanosedimentary group (Ladakh); 16, Mantle ultrabasites (Jijal complex). Unit D MMT-Indus suture zone: 17, Indus Molasses; 18, Spontang ophiolites; 19, Imbricate thrust units, with blue schists. Unit E Higher Himalaya: 20, Neotethyan Sedimentary Group (Permian-Eocene); 21, Tertiary leucogranites (Ladakh and Nanga Parbat); 22, Panjal Traps (Permian); 23, High Himalaya Crystalline (mainly metasediments, Late Proterozoic to early Paleozoic); 24, Paleozoic intrusives (Swat and Manserah Granite, Kohistan; Bhazum and Kade Granite, Ladakh); 25, Basement gneiss (dominantly Early Proterozoic orthogneiss); 26, Besham Metaigneous. Unit F Lesser Himalaya: 27, Paleozoic-Eocene cover; 28, Upper nappe, dominantly Early Proterozoic metasediments (Abbottabad, Kishtwar); 29, Lower nappe, dominantly Late Proterozoic-Paleozoic metasediments (Kishtwar, Kashmir); 30, Salt Ranges (Late Proterozoic-Eocene Indian cover). Unit G sub-Himalaya: 31, Murree and Subatu Formations (Eocene to Miocene); 32, Siwaliks (middle Miocene to Quaternary); 33, Peshawar and Srinagar intramountaneous basins (Quaternary). For seismic hazard analysis, studies of regional geological and tectonic information were collected from the available literature with requisite updates of maps wherever required.

6.2 TECTONIC SETTING

6.2.1 General

From a seismic hazard point of view, the contact zones between adjacent tectonic plates are considered to be the most vulnerable parts to generate earthquakes of varying scales and magnitudes

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

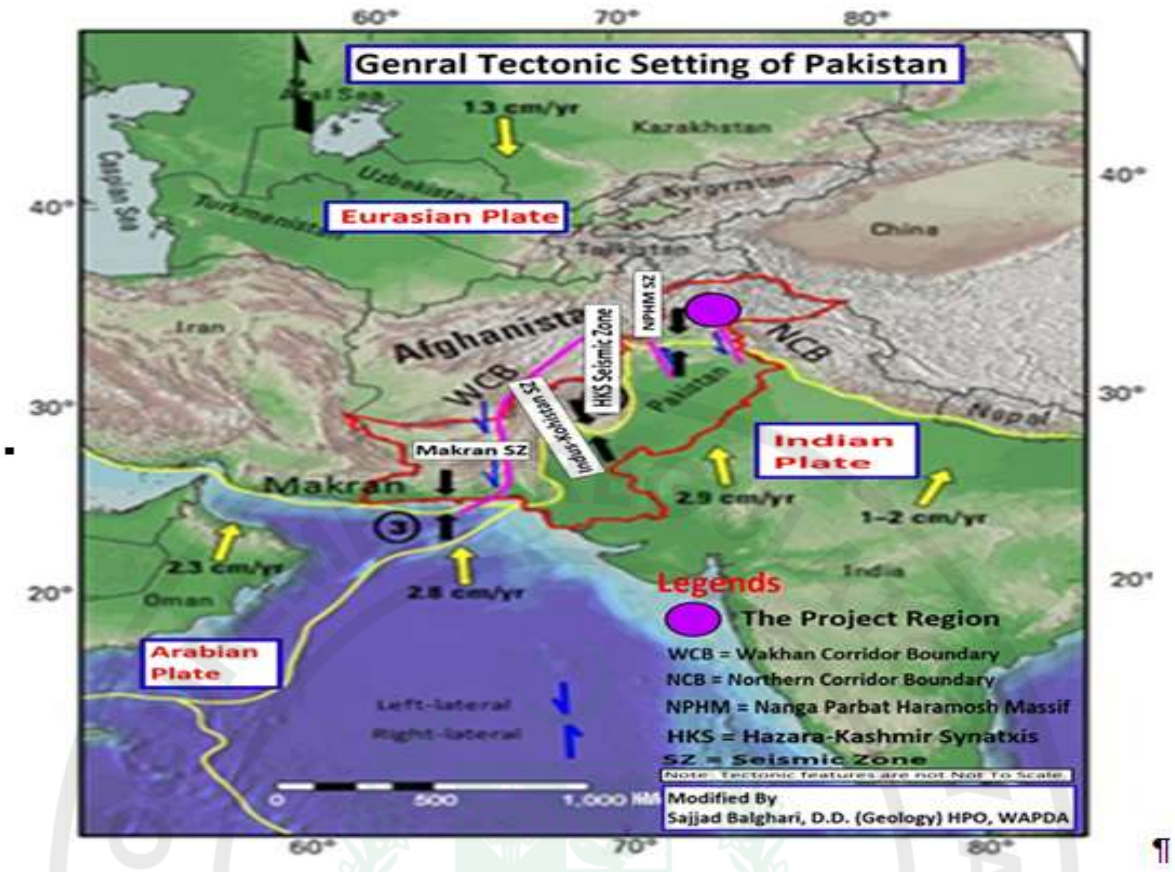

Figure 6-3 General Tectonic Setting of Pakistan.

ALHPP is in the proximity of the collision zone between the north moving Indian Plate and the Eurasian Plate which is over-riding the Indian Plate at a rate of 3 to 4 cm/year as shown in Figure 6-3.

6.3 Regional and Local Tectonic Features

6.3.1 General

The collision tectonics has resulted in the development of a series of geologic faults and the occurrence of frequent earthquakes in Northern Pakistan. The subduction zone of the Indian Plate beneath the Eurasian Plate has resulted in folding and thrusting of the upper crustal layers near the collisional boundary. The distribution of the modern tectonic stress field near Western Himalayan syntaxis is controlled by the collision zone of the Indian Plate and the Eurasian Plate. Due to north and north-east movement of the Indian Plate (Figure 3) in the Northern Pakistan and Kashmir Areas of Pakistan and India, the focal mechanism solution for various earthquakes reflects that the area is under principal compressive stress in the direction of NE-SW and most of the seismogenic faults are thrust fault. The thrusting has been depicted from north to south in the shape of MKT, MMT, MCT, MBT and SRT. Locations of regional and local tectonic features are shown in Figures 6-4 to 6-9.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

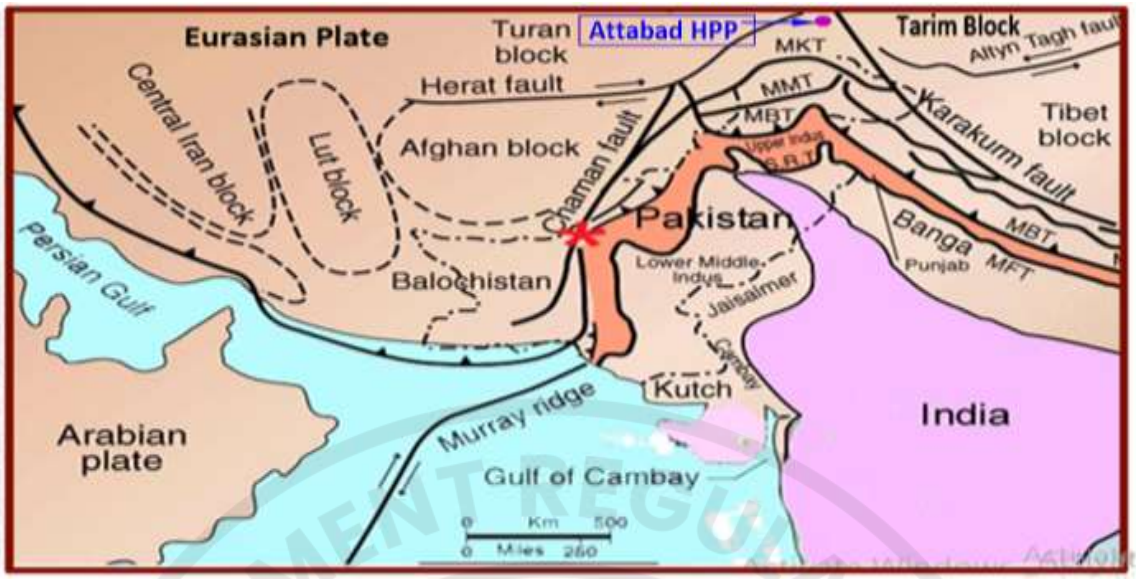

Figure 6-4 Major Tectonic Faults of Pakistan, Pink Circle Shows the Project Area.

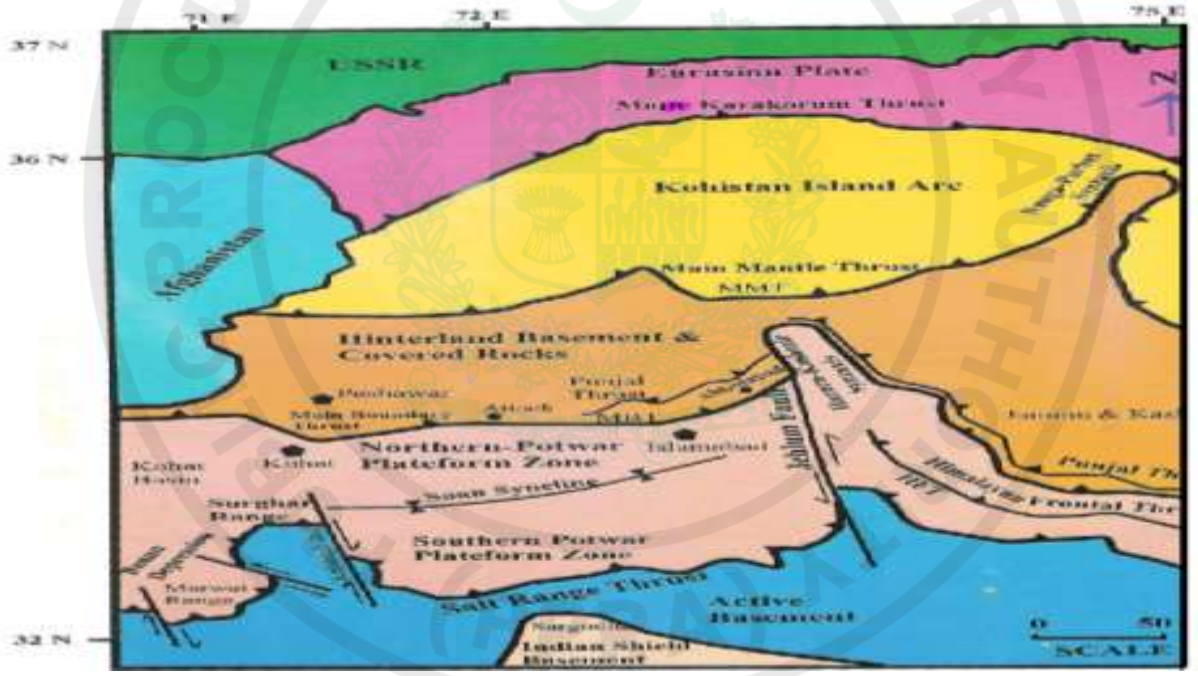

Figure 6-5Tectonic Map of Northwestern Himalayas (Northern Pakistan)
(Reference: Building Code of Pakistan)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

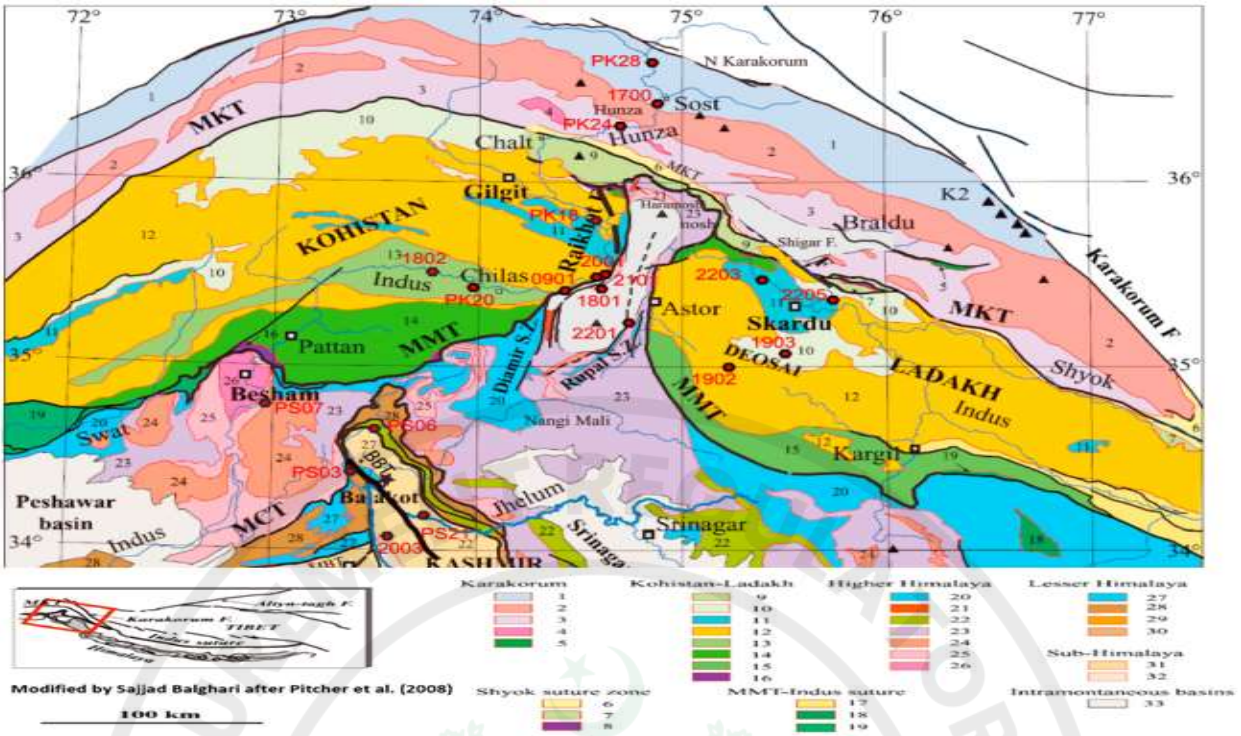

Figure 6-6 Geological Map of Northern Pakistan.

The major faults of region include, from North to South, the Main Karakoram Thrust (MKT), Main Mantle Thrust (MMT), Main Central Thrust (MCT), Panjal Thrust (PT), Nathia Gali Thrust (NGT), Main Boundary Thrust (MBT), Kashmir Boundary Thrust (KBT) / Himalayan Frontal Thrust (HFT) and Salt Range Thrust (SRT) and these faults are shown in Figure 6 to 8. The general trend of these faults is predominantly East-West with change in trend at places due to syntaxial bends.

The brief descriptions of these major faults are as follows: -

6.3.2 HUNZA FAULT (HF)

The upper HF is considered as the northern limit of Main KTF (Pitcher et al. 2008 and Desio et al. 1979) and it is present at the Project Site at a distance of about 1.4 km from the proposed intake / diversion tunnel of ALHPP. It is thrust type fault. It is considered as a major local fault to which is associated with many small local faults in the Project Area.

Although geologically the Project Area is characterized by many local faults and tectonically very disturbed area but the seismic data show that these faults are dormant due to low seismic activity with seismicity class of moderate seismicity at the site as depicted from the analysis of seismic data of the past 200 years.

6.3.3 MAIN KARAKORAM THRUST (MKT)

The MKT is a low angle mega-shear thrust fault with strike slip components as segmented regime at places, which passes through Chalt (near Hunza) on eastern side and extended on western side through Ishkuman and Yasin valleys into Baltistan Area in Hasupa Shigar valley, Machelu in Shyok valley and Shishi valley. In Chitral Area, it encircles the Island Arc Zone on

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

the northern side. Its general trend swings between E and E-NE and dips towards the north at low to medium angle. It is 32 km away from ALHPP towards south. Some segments of this 700 km long thrust fault is seismically active.

6.3.4 MAIN MANTLE THRUST (MMT)

The MKT is a low angle mega-shear thrust fault with strike slip components as segmented regime at places, which passes through Chalt (near Hunza) on eastern side and extended on western side through Ishkuman and Yasin valleys into Baltistan area in Hasupa Shigar valley, Machelu in Shyok and and Shishi valleys. In Chitral area, it encircles the Island Arc Zone on the northern side. Its general trend swings between E and E-NE and dips towards the north at low to medium angle. It is 32 km away from ALHPP towards south. Some segments of this 700 km-long thrust fault is seismically active.

6.3.5 MAIN CENTRAL THRUST (MCT)

It is E-W trending fault separating Higher Himalayas in north and Lesser Himalayas in south, exposed in Upper Kaghan valley, Neelum valley, Northern Hazara, Swat and Dir (chaudhary et. al, 1994). Generally, it is a ductile shear zone along which a distinct break in metamorphism is observed along this thrust, toward North, metamorphism of upper amphibolites to eclogite facies took place while to the south, green schist facies are present. It is seismically active fault.

6.3.6 PANJAL THRUST (PT)

PT is nearly NW–SE trending fault on Eastern side, bending at 180° around Hazara Kashmir Syntaxis (HKS) and have NE-SW trend on Western side, separating Lesser Himalayan Igneous and Metamorphic Zone in the north from Sedimentary Zone in the south. It traces Eastward in Kashmir basin, at the foot hill of Pir-Panjal ranges through India and extends westward through Mansehra, Attock, Nowshera, Peshawar and Afghanistan. It is seismically active fault.

6.3.7 NATHIA GALI THRUST (NGT)

It is nearly NE-SW trending thrust originates from Western side of Hazara Kashmir Syntaxis (HKS) extends westward through Hazara area (well exposed in Jabri and Khanpur Area) and Kala Chitta Ranges to Afghanistan. It is low angle fault along which Tertiary rocks are in contact with Precambrian rocks (slates). It is seismically active fault.

6.3.8 MAIN BOUNDARY THRUST (MBT)

The MBT is the most significant and active tectonic feature of regional extent separating Lesser Himalayas in the north from Sub Himalayas in the south. It runs along the Himalayan Arc for about 2800 km from the Asam in the east to Kashmir and Parachinar in the west. MBT along with other associated thrusts forms a sharp conspicuous Hazara-Kashmir Syntaxis(HKS). This syntaxial bend is the most dominant tectonic feature of the area as all local major fault systems and geologic structures follow its trend. Near its surface trace the MBT dips Northward at a steep angle, which becomes sub horizontal with depth. The Project Area is located to the North of this fault. It is also seismically active fault.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6.3.9 KASHMIR BOUNDARY THRUST / HIMALAYAN FRONTAL THRUST (KBT/HFT)

It is nearly NW-SE trending fault coming from India which become nearly NW and SE trending thrust near Kotli, joins HKS, northward with other faults in the Western epical portion. Toward south passing through Garhi Habib Ullah, Muzaffarabad, Domel and Kotli, runs eastward to India. A devastating earthquake of October 08, 2005 having magnitude 7.6 on scale is associated with rupture along this fault having epicenter, about 10 km upstream of Muzaffarabad in Gohri-da-Katha (right tributary of Neelum River).

6.3.10 SALT RANGE THRUST (SRT)

It is seismically active fault along which Precambrian rock e.g. SRF is exposed. It separates the Sub Himalayas from Punjab Plains. It is dissected Westward by Kalabagh Fault, a right lateral strike slip fault and eastward by Jhelum Fault, a left lateral strike slip fault.

6.4 SEISMICITY OF PROJECT AREA

6.4.1 General

The Project Area lies in the region of Northern Pakistan which has high frequency of earthquakes especially in the Himalayan Orogenic Belt. This belt represents the contact between Indo-Pak and Eurasian Plates, which has always been the source of moderate to large earthquakes including Kangra (1905), Bihar-Nepal (1934), Assam (1897) and 2005 Kashmir earthquakes with significance consequences. The presence of some of the active faults like MKT, MMT, Raikot Fault, Riwat Fault, Panjal Khairabad Fault, Jhelum Fault and MBT etc. make the Northern Pakistan region tectonically very active. However, in this area of dominantly collisional tectonics, a large number of focal mechanism solutions indicate thrust faulting with some strike-slip faulting as segmented faulting system (Fitch, 1970; Rastogi, 1974; Armbruster et al., 1978; Verma et al., 1980; Verma and ChandraSekhar, 1986; Molnar and Lyon Caen, 1989; Pivnik and Sercombe, 1993, MonaLisa et al., 1997, MonaLisa et al., 2003 and Khwaja et al., 2003). A kinematic change from compression to transgression is believed to be taking place at places (Pivnik and Sercombe, 1993). Both historical / non instrumental and instrumental data exist in the area. The instrumentally recorded earthquake data are available only since 1904. Seismic hazard analysis involving the quantitative estimation of ground shaking hazards is of great importance for hydropower projects proposed in seismically active zones. The region selected for acquiring tele-seismic catalogues is shown as brown rectangle in the satellite map given as Figure 6-10.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

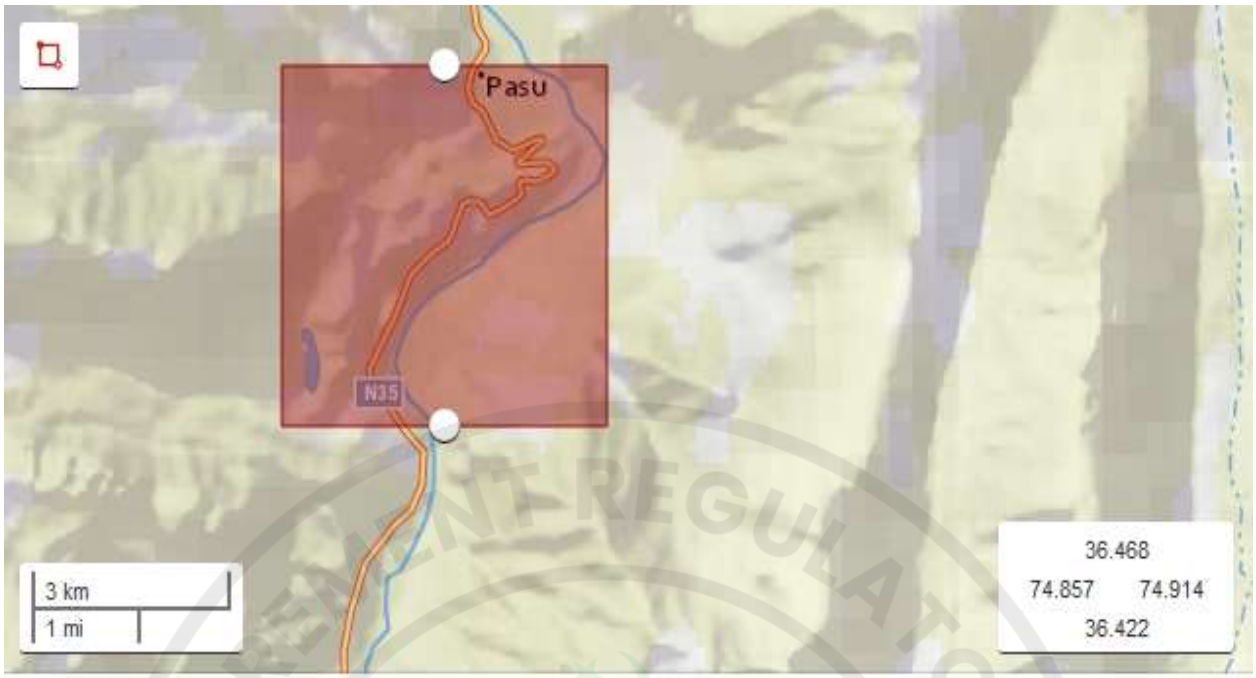

Figure 6-10 Region Selected for Acquiring Tele-seismic Earthquakes Catalogue

6.4.2 STUDY AND ANALYSIS OF EARTHQUAKES DATA

Study and analysis of the earthquake record involved several activities including;

a. Investigation of the historical seismicity
b. Acquiring earthquake catalogues both international and national catalogues including WAPDA earthquakes catalogue
c. Examination of instrumentally recorded earthquake record.
d. Statistical analysis of catalogue data and determination of standard deviation.
e. Determination of input values such as upper maximum magnitudes, minimum magnitudes, b-values, beta, lamda, rupture etc. for each seismic source.
f. Interpretative description of the new scenario after Kashmir Earthquake of October 8, 2005
g. Analysis of the earthquake records (both historical and instrumental data)
h. Preparation of seismicity maps.
i. Presentation of interpreted results including focal mechanisms etc.

Both historical and instrumetal records of earthquakes were acquired from international and national agencies for compilation of updated composite catalogue.

For seismic hazard assessment, the guidelines provided by International Commission on Large Dam (ICOLD, Bulletin 148, 2016) for selecting seismic parameters for large dams has been followed. For preparation of input maps in acceptable formats (i.e. shape files), ArcGIS and Surfer softwares were used.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

For performing seismic hazard analysis, the latest version of R-CRISIS V.20.1.1 and Ez-Frisk Software were used with a purpose of comparison of results and cross checking for validation testing.

6.4.3 Historical (Pre-Instrumental) Seismicity

The historical pre-instrument earthquake data for GB has been collected from the literatures and non-instrumental earthquakes catalogues such as catalogues of Oldham, 1893, Heukroth and Karim, 1970, Ambraseys et al. 1975 and Quittmeyer and Jacob, 1979 and other national and international sources as shown in Figure 6-11.

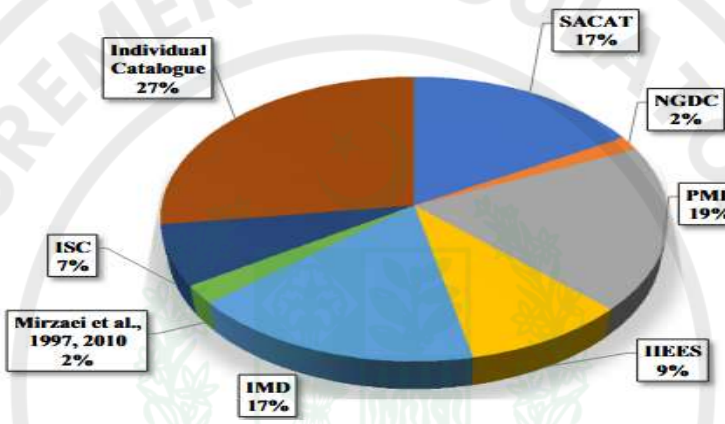

Figure 6-11 Pie Chart of Historical Sources for Compilation of Composite Earthquake Catalogue.

6.4.4 Analysis of Historical (Pre-Instrumental) Seismicity

The analysis of historical earthquake data reflects that Northern Pakistan as a whole has remained a house of prominent earthquakes but the events are sparse at the Project site (please refer to Figure 5). Taxila earthquake (25 A.D.) event is probably the most conspicuous one that had changed style of building-construction after the devastating event.

However, the catalogue of historical earthquakes for GB Region is rather sparse, mainly due to remoteness of this hilly terrain as well as non-availability of local seismic networks in the area. Since the 1700's, the historical earthquake data for GB are few and mainly concentrated on the centres of colonial administration. However, the situation is now improving as WAPDA is extending its seismic stations with the passage of time.

In the present analysis of historical earthquakes around ALHPP, the analysis of historical earthquake events was performed in Ez-Frisk Software using the historical earthquakes database and the analyzed results is presented as Figure 6-12.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

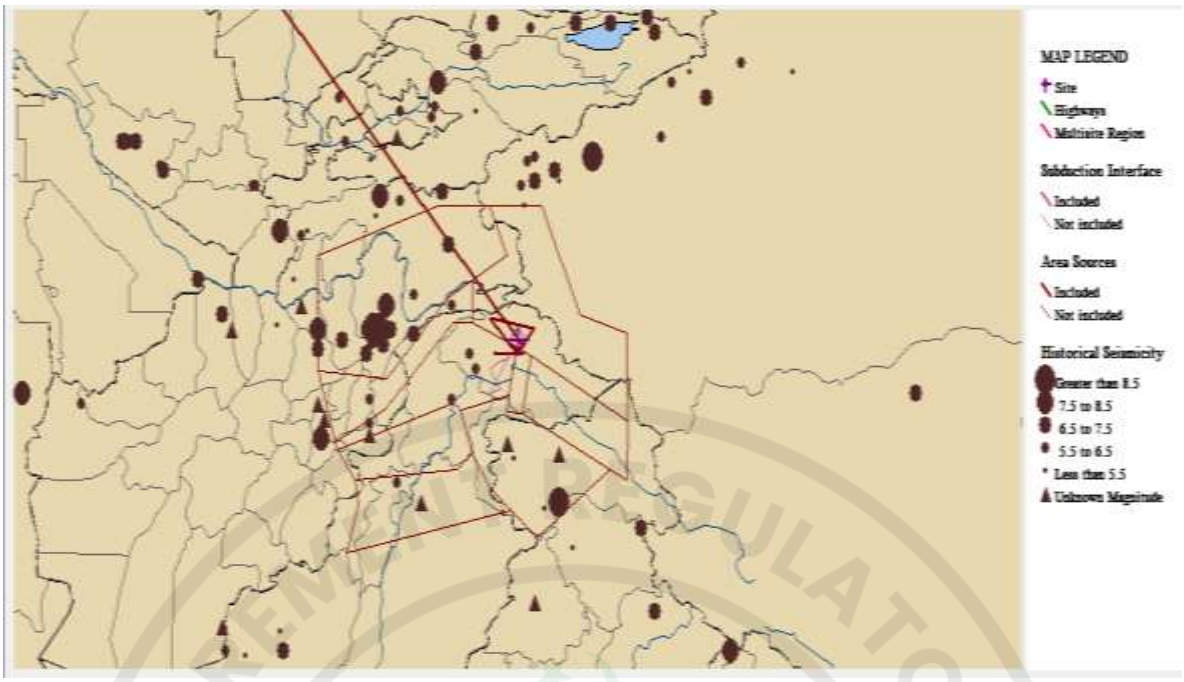

Figure 6-12 Historical Earthquakes Map around ALHPP and Adjoining Areas Analyzed in Ez-Frisk Software.

6.4.5 Instrumental Seismicity

The instrumental recording of earthquakes started in 1904 but very few seismic stations were established in the South Asian Region until the 1960's. However, with the installation of high quality seismographs under the World Wide Standard Seismograph Network (WWSSN) established by the U.S. Coast and Geodetic Survey in 1960, the quality of earthquake recording in this Region improved and resulted in a better understanding of the seismicity of Pakistan as well.

In Pakistan and most other parts of the World, the seismic record is too short and incomplete to develop a complete sample that is truly representative of the spatial and temporal distribution of earthquake shocks over a large period. Nevertheless, all the available information has been gathered for the period covering the last century, which was used to develop a satisfactory and safe assessment of seismic hazard for the Project.

For this study, the instrumental record of earthquakes within a radial distance of about 200-km of the Project was searched and acquired from both international and national sources as shown in Figure 6-13.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

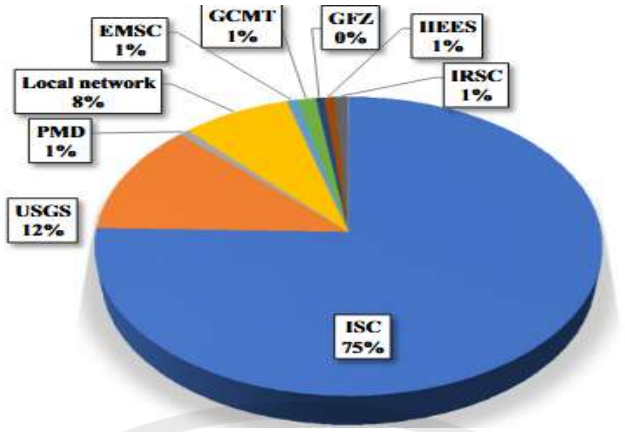

Figure 6 -13 Pie Chart of Instrumental Sources Contributing to the Compilation of Composite Earthquake Catalogue

6.4.6 Analysis of Instrumental Seismicity

The spatial and temporal distribution of the earthquakes events with magnitudes of the past 100 years at and around the ALHPP Site is shown as Figure - 14 &15. The seismicity within a 200 km radius of the Project Site were analyzed using the composite catalogue and the results are presented in Figures 6-12 to 6-18**.**

Hunza Fault exists within the Project Area at a distance of 2.4 km from weir site whereas the MKT is the second nearest fault, located at a distance 32 km from Project Site and the last limit of the MMT is at a distance of 71.69 km away from the Project Site (please refer to Figure - 2).

According to the field geologists who carried out geological mapping at the site, there are many micro faults and neotectonic features at site which shows that the Project Area is tectonically very disturbed. However, the analysis of the seismicity data (both historical and instrumental) shows that earthquake events are not concentrated in the Project Area. (please refer to Figures 6-7 to 6-12**).** The comparison and correlation of seismicity analysis with tectonic and geologic data lead to the understanding that the geologic deformations including micro faults may be viewed as deformations tectonically associated with MKT which triggered its associated splays and surrounding tectono-geologic environment in the past.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

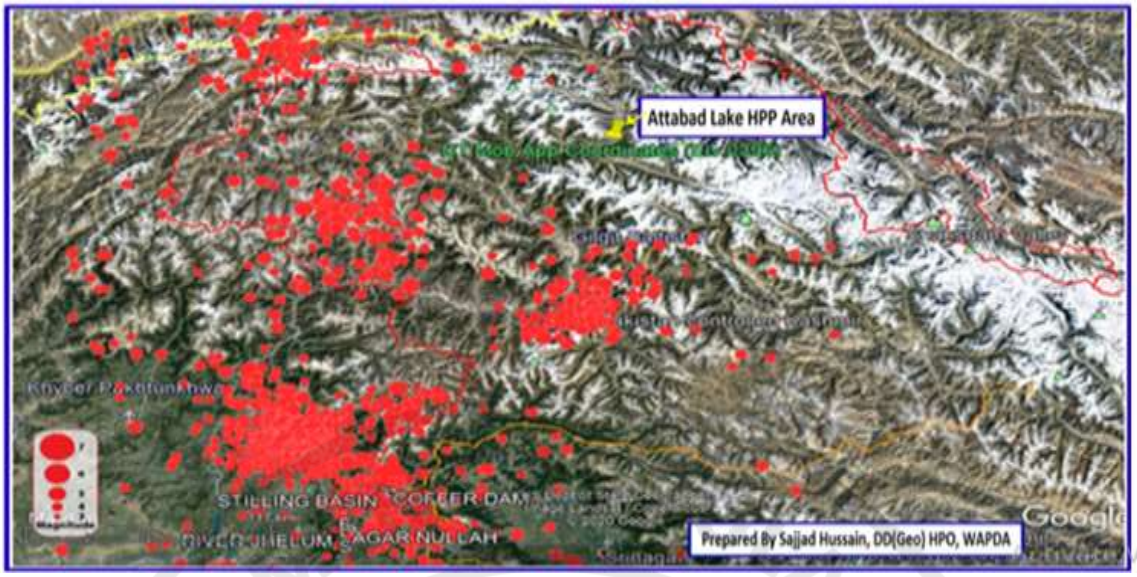

Figure 6 14 Temporal Distribution of the Earthquakes Events with Magnitudes of the Past 100 Years, Pink Rectangle Shows ALHPP Site.

As can be seen from instrumentally recorded earthquake events of the past 100 years data (Figure 6-14) and historical earthquakes around the Project Site (Figure 6-12) that there is very low concentration of earthquake events around the Project Site. However, if local micro-seismic network is installed at the Project Area at belated stages, more coverage and representation of the earthquakes events may result at belated stages. Analysis of the composite earthquakes catalogue data shows that the nearest magnitude at the Project Site is M4.7 and the maximum magnitude nearest to the site is M5.2. as shown in figure 6-15

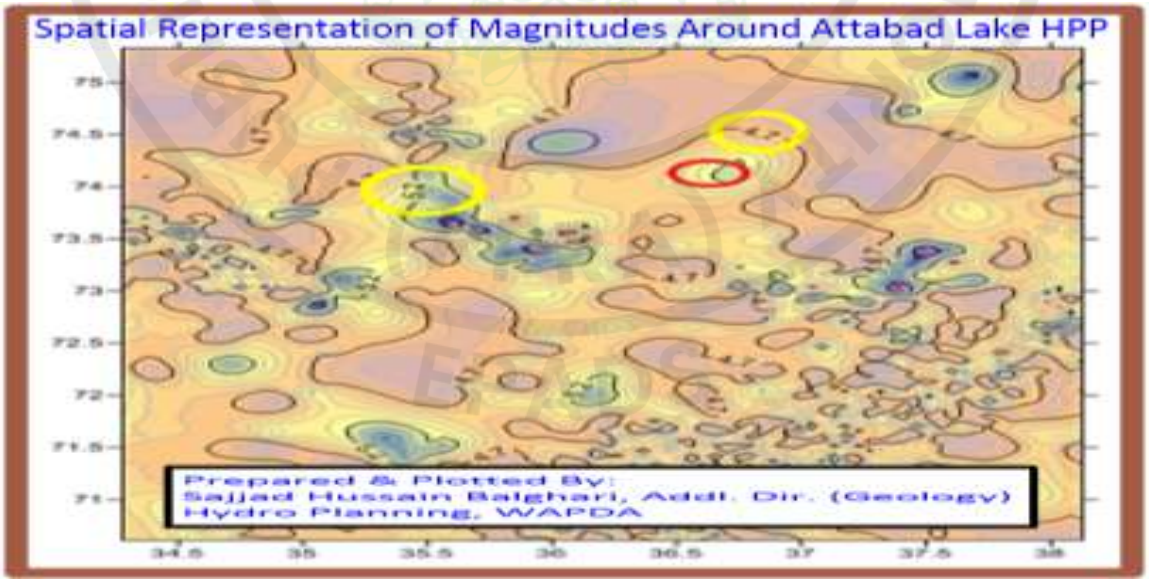

Figure 6-15 Distribution of Earthquake Magnitudes of the Project Area (Red Circle Shows the Project Area).

A composite map showing seismic basins of Pakistan and Hunza Area and Seismic Zonation map of Building Code of Pakistan (2007) covering historical earthquakes data is presented as

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Figure 6-16 which shows that the maximum magnitude of the Project Region (Hunza-Nagar) is M 6.1.

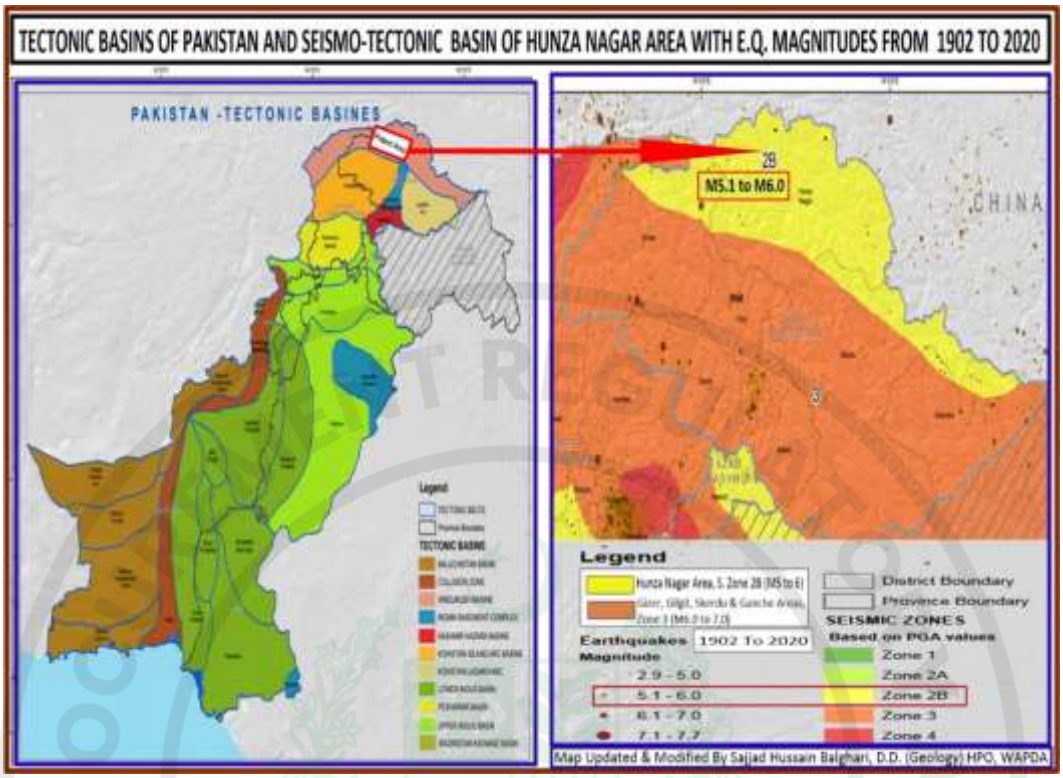

Figure 6-16 Composite Map Showing Seismic Basins of Pakistan and Hunza Area and Modified Seismic Zonation Map (Revised Building Code of Pakistan, 2007)

However, in the present seismic hazard analysis, the maximum magnitudes for the near-field seismic sources for the Project Site has been conservatively assigned higher in seismic hazard assessment for the Project keeping the safety factors in view as well as perceiving the tectonic scenario of Hunza Fault as a splay of MKT.

Earthquakes depth map developed from composite earthquakes catalogue data at and around the ALHPP Area is presented as Figure 6-17

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

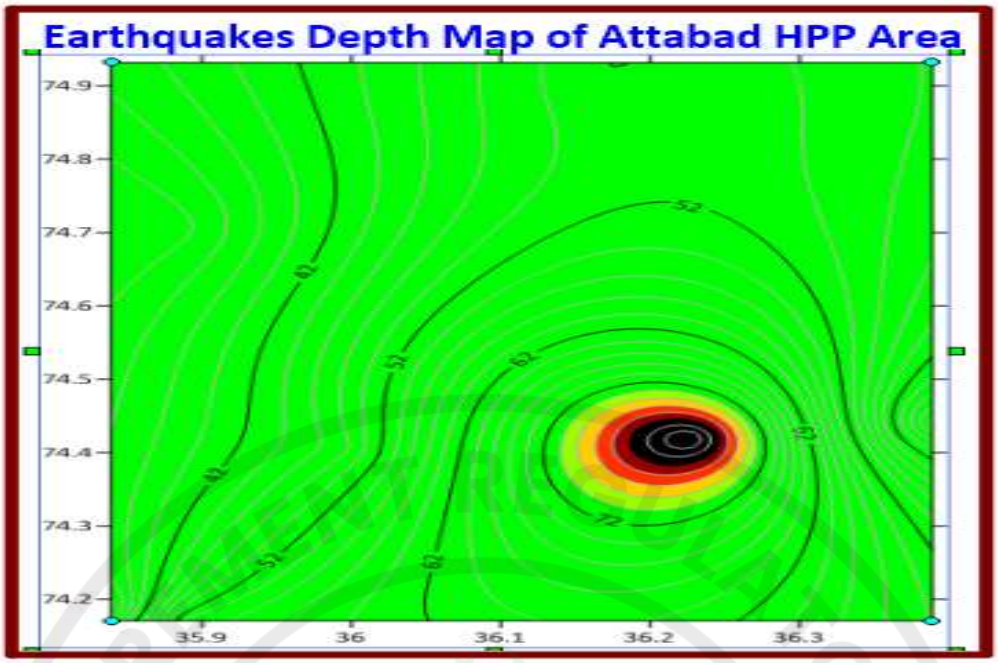

Figure 6-17 Earthquakes Focal Depth Contour Map of ALHPP Area. The Black Circle Shows the Dam / Weir Site and the Nearest Focal Depth to the Site is 72 km.

A composite seismic map showing both historical and instrumental earthquakes events for the past 1255 years (765 A.D. to 2020) is presented as Figure 6-18

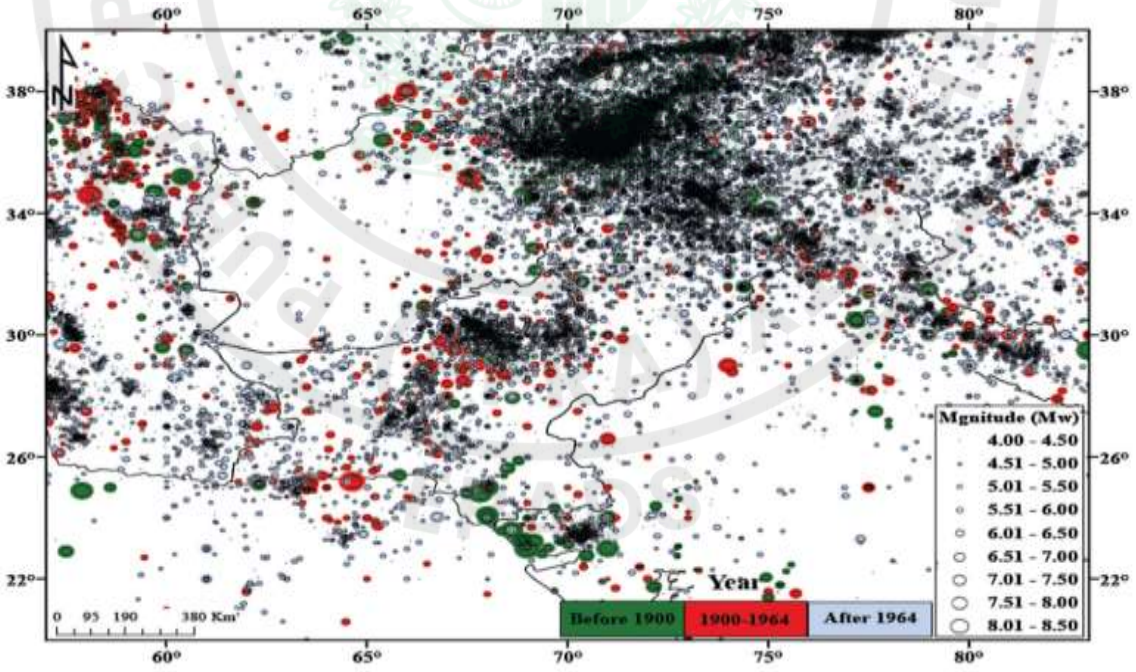

Figure 6-18 Seismic Map Showing Events with Magnitudes of the Past 1255 Years (765 A.D. to 2020).

6.4.1 Conversion of Magnitudes and Standard Deviation

The earthquakes reporting agencies have given a variety of magnitudes viz: Body-wave magnitude (m_b), Surface-wave magnitude (M_S), Richter/Local magnitude (M_L) or Duration-

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

magnitude (M_D) etc. Since ground motion prediction equations are based on magnitude of given type, a single type must be selected. For data to be used in seismic hazard analysis, all these different magnitudes were converted to moment magnitude (M_W) by the following equations.

Conversion from M_S and m_b to M_W was achieved through latest equation suggested by Scordilis (2006):

$M_W = 0.67\ M_S + 2.07$ for $3.0 \leq M_S \leq 6.1$

$M_W = 0.99\ M_S + 0.08$ for $6.2 \leq M_S \leq 8.2$

$M_W = 0.85\ m_b + 1.03$ for $3.5 \leq m_b \leq 6.2$

For M_L up to 5.7, the value of M_L was taken equal to M_W as suggested by Idriss (1985) and supported by operators of local networks in Pakistan. Conversion of M_L to M_W beyond magnitude 5.7 was done by using the following equations suggested by Ambraseys and Bommer (1990) and Ambraseys and Bilham (2003):

$0.82\ (ML) - 0.58\ (MS) = 1.20$

$\text{Log Mo} = 19.09 + MS$ for $MS < 6.2$

$\text{Log Mo} = 15.94 + 1.5\ MS$ for $MS > 6.2$

$MW = (2/3)\ \text{Log}\ (Mo) - 10.73$

Where m_b is body–wave magnitude, M_S is surface-wave magnitude, M_L is local magnitude, All available types of magnitudes in the catalogue were converted into a uniform magnitude-scale i.e. M_W (Moment magnitude). Observed dependence of б (standard deviations) on Moment Magnitudes is given is Figure 19. The earthquakes reporting agencies have given a variety of magnitudes viz: Body-wave magnitude (m_b), Surface-wave magnitude (M_S), Richter/Local magnitude (M_L) or Duration-magnitude (M_D) etc. Since ground motion prediction equations are based on magnitude of given type, a single type must be selected. For data to be used in seismic hazard analysis, all these different magnitudes were converted to moment magnitude (M_W) by the following equations.

Conversion from M_S and m_b to M_W was achieved through latest equation suggested by Scordilis (2006):

$M_W = 0.67\ M_S + 2.07$ for $3.0 \leq M_S \leq 6.1$

$M_W = 0.99\ M_S + 0.08$ for $6.2 \leq M_S \leq 8.2$

$M_W = 0.85\ m_b + 1.03$ for $3.5 \leq m_b \leq 6.2$

For M_L up to 5.7, the value of M_L was taken equal to M_W as suggested by Idriss (1985) and supported by operators of local networks in Pakistan. Conversion of M_L to M_W beyond magnitude 5.7 was done by using the following equations suggested by Ambraseys and Bommer (1990) and Ambraseys and Bilham (2003):

$0.82\ (ML) - 0.58\ (MS) = 1.20$

$\text{Log Mo} = 19.09 + MS$ for $MS < 6.2$

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Log Mo = 15.94 + 1.5 MS for MS > 6.2

MW = (2/3) Log (Mo) – 10.73

Where m_b is body–wave magnitude, M_S is surface-wave magnitude, M_L is local magnitude, All available types of magnitudes in the catalogue were converted into a uniform magnitude-scale i.e. M_W (Moment magnitude). Observed dependence of ϭ (standard deviations) on Moment Magnitudes is given is Figure 6-19

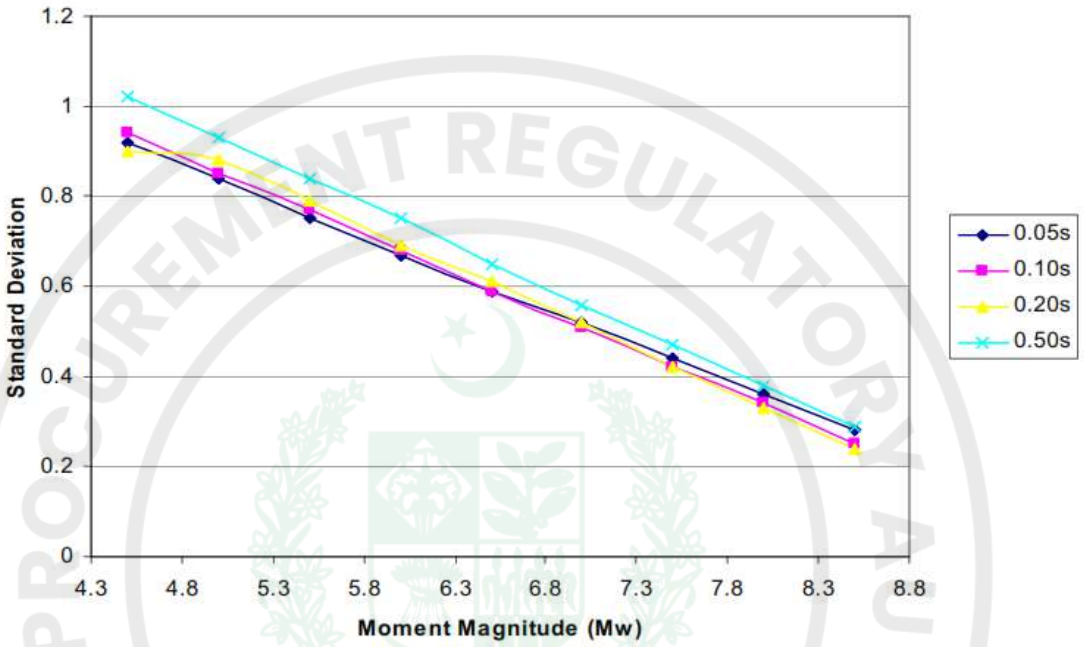

Figure 6-19 Standard Deviations (ϭ) Vs Moment Magnitudes (Mw).

6.4.2 Kashmir Earthquake (M 7.6) of October 08, 2005 and the New Scenario

The powerful earthquake with a magnitude of M_W =7.6 that struck the northern part of Pakistan and Kashmir on October 08, 2005, caused widespread damage in Azad Kashmir and adjoining areas of KPK. This prompted for consideration of re-activation of previously perceived dormant faults segments as active fault segments in the new scenario.

The epicenter of this earthquake was located northeast of Muzaffarabad. This earthquake was felt for several minutes in Pakistan, northern India, and Afghanistan. The heaviest damage was recorded in the towns of Balakot, Batal, and Batagram in KPK and Muzaffarabad, Bagh and Rawalakot in Azad Kashmir where the entire population was badly affected. Building collapse were also reported in Muzaffarabad, Mansehra, Abbottabad, and Islamabad. Severe cracks were observed in many high-rise buildings in Islamabad too. The death toll due to this earthquake exceeded 80,000 people and millions were rendered homeless due to collapse of houses. The earthquake was followed by a series of more than thousand aftershocks, hundreds of them exceeding magnitude M 4.0. This earthquake was caused by the movement due to rupture along a thrust fault named the “Balakot-Bagh Thrust” (BBT) which is a northern most branch of the MBT like Riasi Thrust, a main branch of the MBT in Kashmir as shown in Figure 6-20. Ground ruptures and fresh landslides have been observed along this fault at many places near Muzaffarabad and Balakot.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

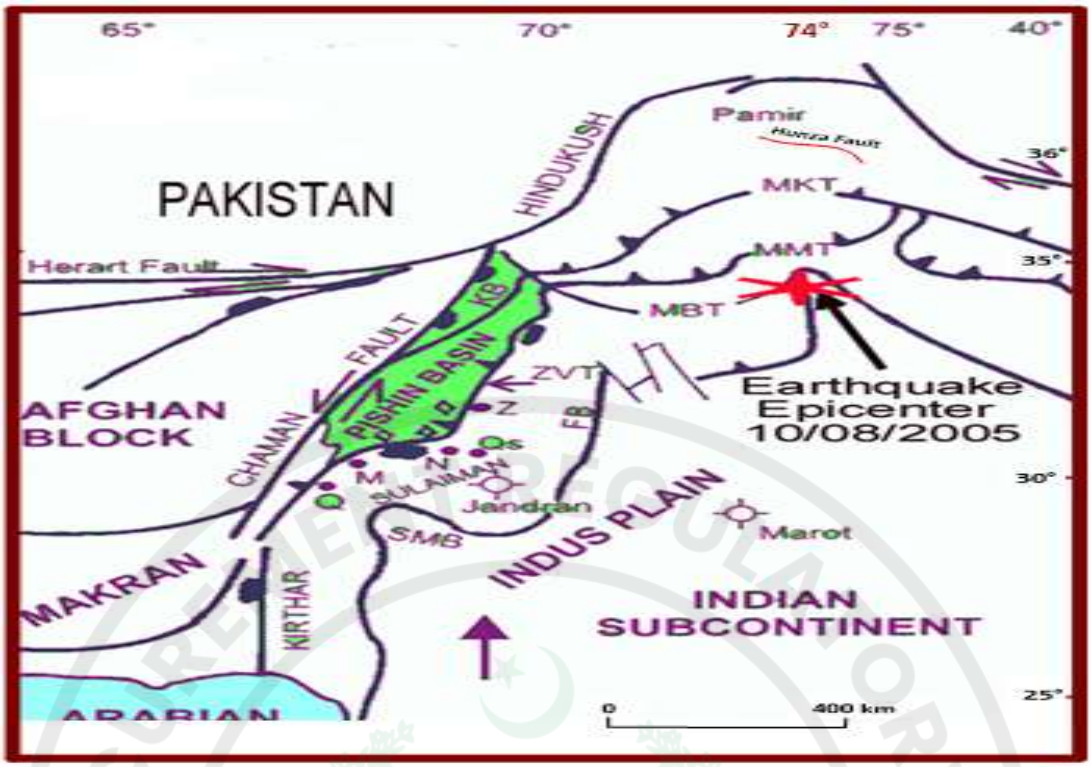

Figure 6-20 Earthquake Epicenter of Kashmir Earthquake of October 8, 2005.

Thus, the Kashmir earthquake of 8th October, 2005 has changed the scenario of seismic design in Pakistan and prompted for design review of Neelum Jhelum Hydropower Project where MBT and Panjal Thrust are crossing the dam area. These two faults were previously considered as dormant faults. After the earthquake of 8th October, 2005, these two faults were considered as active faults and seismic design parameters were reviewed and changed to the much safer side resulting in massive cost overruns. The new scenario also prompted to revise Building Code of Pakistan which was revised and updated in 2007 accordingly thereby enhancing the design parameters in the new scenario. Hence, previously adopted design codes and parameters were considered as under estimated and began to enhance the safety factors in seismic design for buildings and ordinary structures in Pakistan. In the wake of the new scenario seismic design parameters of dams and water retaining structures are also being given due importance towards conservative sides.

Since the revision of Next Generation Attenuation relations by Pacific Earthquakes Engineering Research Center (PEER) of USA in 2014, seismic safety factors are being given due considerations as per ICOLD's Revised Guidelines given in Bulletin 148 (2016).

The present analysis is in line with these national and global developments. In the present seismic hazard analysis, the latest ground motion prediction equations known as NGA West 2 Attenuation Relations (2014) have been used and the latest version of R-CRISIS software Ver 20.1.1. and Ez-Frisk Ver 7.65 have been used for seismic hazard analysis of ALHPP.

6.5 INDENTIFICATION OF SEISMIC SOURCES

Based on the understanding of the analysis of seismicity, tectonic setting, major faults of the area and area-seismic related seismogenic features within 200 km radial distance of the Project Site, the area seismic sources for the Project include Karakorum Seismic Zone, Nanga Parbat-Haramosh Seismic Zone, Western Himalayas Seismic Zone, Hindukush Seismic Zone, Kashmir Himalayas Seismic Zone and Kohistan Seismic Zone.

The significant point seismic sources (faults) capable of generating earthquakes for ALHPP, include;

a. Hunza Fault (Thrust Fault)
b. Main Karakoram Thrust (MKT),
c. Main Mantle Thrust (MMT)

The area seismic sources within a radial distance of 200km include

Quantitative features of these controlling faults are given in tabulated form in Table 1.

Table 6-1 The Controlling Faults with Quantitative Features (input values of DSHA)

Controlling Faults	Fault Type	Fault Rupture Length (km)	Distance (km)	Maximum Magnitude Potential	
				As per Catalogue data	Conservatively Assigned
Hunza Fault	Thrust	5 inferred	1.4	6.1	6.7
MKT	Thrust	200	32	7.0	7.6
MMT	Thrust	260	71.69	6.9	7.6

Brief description of the seismogenic sources for the Project is given below,

6.5.1 HUNZA FAULT (HF)

The upper HF is considered as a splay fault of MKT (Pitcher et al. (2008) and as the northern limit of MKT (Desio 1979). It is present at the Project Site at a distance of about 1.4 km from the proposed intake / diversion tunnel of ALHPP (Figure 2). It is thrust type fault. Associated with HF, there are many small local faults with unknown fault parameters such as rupture length etc. in the area. Presence of HF and many minor local faults along with some neotectonic features as reported by site geological mapping indicate that the fault is active. However, analysis of tele-seismic data for the last 100 years shows that the Project Area has low concentration of earthquake events with seismicity class of low to moderate seismicity and there has been no earthquake activity greater than magnitude 5.2 as per analysis of composite catalogue.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6.5.2 MAIN KARAKORUM THRUST (MKT)

The MKT is a low angle mega-shear thrust fault with strike slip components as segmented regime at places, which passes through Chalt (near Hunza) on eastern side and extended on western side through Ishkuman and Yasin valleys into Baltistan Area in Hasupa Shigar valley, Machelu in Shyok valley and and Shishi valley. It encircles the Island Arc Zone on the northern side in Chitral Area. Its general trend swings between E and E-NE and dips towards the north at low to medium angle.

MKT is located at a distance of 32 km from ALHPP towards south (Figure 6-2). Some segments of this 700km-long thrust fault is seismically active.

6.5.3 MAIN MANTLE THRUST (MMT)

The MMT, which is aligned with the Nanga Parbat-Haramosh Massif (NPHF) tectonically, spans over an area of about 400 km through Diamer, Kohistan, and Bajour, before entering Afghanistan. The general trend of MMT is NE-SW. It is located along the contact of the mafic/calc-alkaline meta igneous rocks and the meta-sediments belonging to the Indo-Pakistan continental mass. Along this megashear near Jijal village on Indus River (right bank), the igneous rocks have overthrusted the meta-sediments to the south over a 10-15 km wide zone. The thrust also manifests as the broad high topography of Kohistan relative to the Hazara to the south. In addition, numerous auxiliary fractures were developed and across the thrust frequent brecciation and mylonitization are also present along the contact. Some segments of MMT is seismically active. Due to its seismic activity and tectonic impacts, this fault has also been considered in seismic hazard assessment of ALHPP.

The last limit of MMT nearest to the Project Area is located at a distance of 71.69 Km from ALHPP (Figure 6-2).

The above mentioned faults have been used in DSHA approach. However, in PSHA approach, area seismic sources have been used in the present study, being more reliable as compared to point sources.

The used area seismic sources include Karakorum Seismic Zone, Nanga Parbat-Haramosh Seismic Zone, Western Himalayas Seismic Zone, Hindukush Seismic Zone, Kohistan Seismic Zone and Kashmir Himalayas Seismic Zone.

6.6 SEISMOTECTONICS

From the available tectonic and seismic data, seismo-tectonic analysis of ALHPP was done. Seismo-tectonic map of ALHPP and Northern Pakistan showing the seismic concentrations over active seismic sources have been developed and are presented as Figures 6-21 and 6-22.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

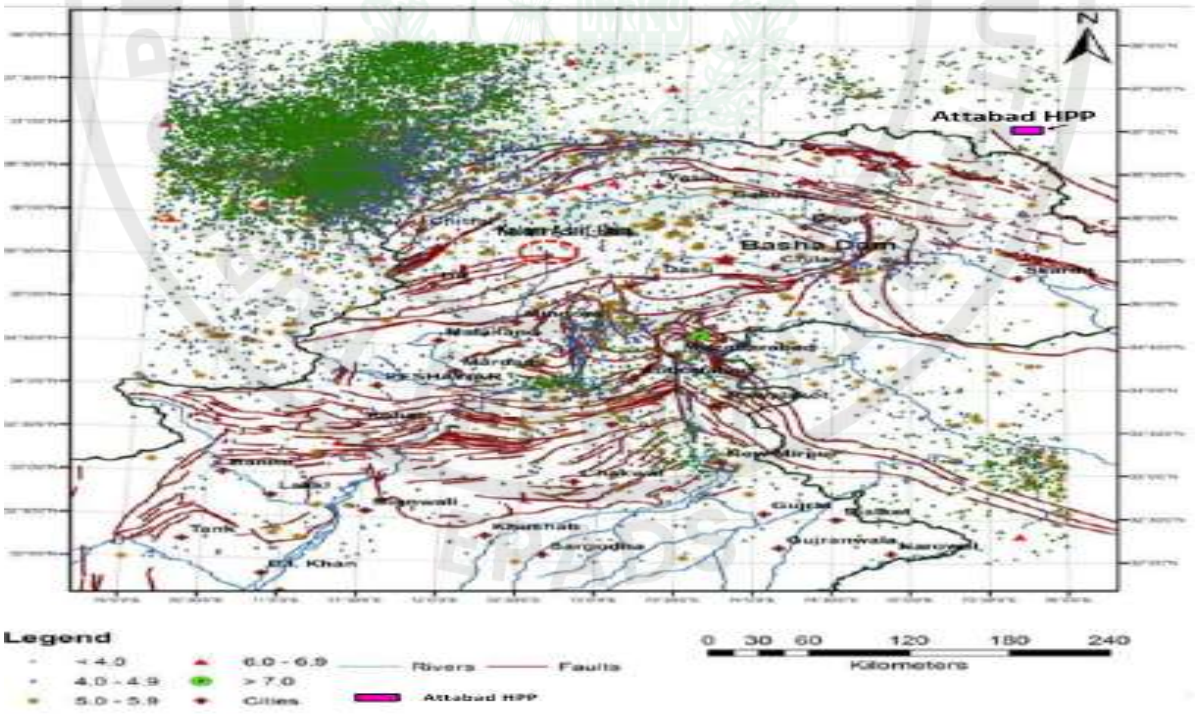

Figure 6-22 Seismo-Tectonic Map of Northern Pakistan Showing Project Area.

6.7 PROBABILISTIC SEISMIC HAZARD ASSESSMENT (PSHA)

6.7.1 PSHA Methodology

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The principle of the analysis, first developed by Cornell (1968) and later refined by various researchers, is to evaluate at the site of interest the probability of exceedance of a ground motion parameter (e.g. acceleration) due to the occurrence of a strong event around the site. This approach combines the probability of exceedance of the earthquake size (recurrence relationship), and probability on the distance from the epicenter to the site. Each seismic source zone is divided into elementary source zones at a certain distance from the site. Integration is carried out within each zone by summing the effects of the various elementary source zones taking into account the attenuation effect with distance. Total hazard is finally obtained by adding the influence of various sources. The results are expressed in terms of a ground motion parameter associated with return period (return period is the inverse of the annual frequency of exceedance of a given level of ground motion). The seismic hazard model used in the present analysis was developed based on both area source as well as fault sources in the light of findings of the seismotectonic synthesis. Each seismic source zone is defined as a zone with homogenous seismic and tectonic features, inferred from geological, tectonic and seismic data. These zones are first defined, and then a maximum earthquake and an earthquake recurrence equation are elaborated for each of these seismic source zones. The present work is the first of its kind in which both NGA West 1 and NGA West 2 ground motions equations have been used for seismic hazard assessment of ALHPP.

The seismic parameters attached to the various seismic source zones are: a recurrence relationship relating the number of events for a specific period of time to the magnitude; the maximum earthquake giving an upper bound of potential magnitude in the zone; and an attenuation relationship representing the decrease of acceleration with distance. The PSHA requires a detailed analysis of distribution of observed seismic data to the seismic sources, determination of b-value and activity rate of each seismic source and assigning maximum magnitude potential to each seismic source.

6.7.2 Earthquake Recurrence Model

A general equation that describes earthquake recurrence may be expressed as follows:

$$N(m) = f(m, t) \qquad (1)$$

Where N (m) is the number of earthquakes with magnitude equal to or greater than m, and t is time period.

The simplest form of equation (1) that has been used in most engineering applications is the well-known Richter's law which states that the cumulated number of earthquakes occurred in a given period of time can be approximated by the relationship

$$\text{Log } N(m) = a - b\,m \qquad (2)$$

Equation (2) assumes spatial and temporal independence of all earthquakes, i.e. it has the properties of a Poisson model. Coefficients 'a' and 'b' can be derived from seismic data related to the source of interest. Coefficient 'a' is related to the total number of events occurred in the source zone and depends on its area, while coefficient 'b' represents the coefficient of proportionality between log N (m) and the magnitude.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The composite catalogue of earthquakes prepared for the ALHPP Area provided the necessary database for the computation of b-value for each seismic area source zone. The composite earthquake list contains limited number of earthquakes prior to 1960 and only few of these earthquakes have been assigned magnitude values. Due to installation of WWSSN, the earthquake recording in this region improved and a better and complete recording of earthquake data are available after 1960. The completeness analysis of the overall data for the region showed that earthquake data up to magnitude 4.0 is complete after 1960.The converted moment magnitude for the period between 1961 and 2020 was therefore used in the PSHA after excluding the aftershocks. Magnitude-frequency curves were made for each seismic area source and presented as Figure-23. The b-value for each seismic area source zone was calculated using linear regression through least square method. The minimum magnitude for each area source zone was selected from the magnitude-frequency curve based on completeness checks suggested by Woeffner and Weimer (2005). The b–values, minimum magnitude and the activity rates for the seismic area source zones used in the PSHA are shown in Table 6-2.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

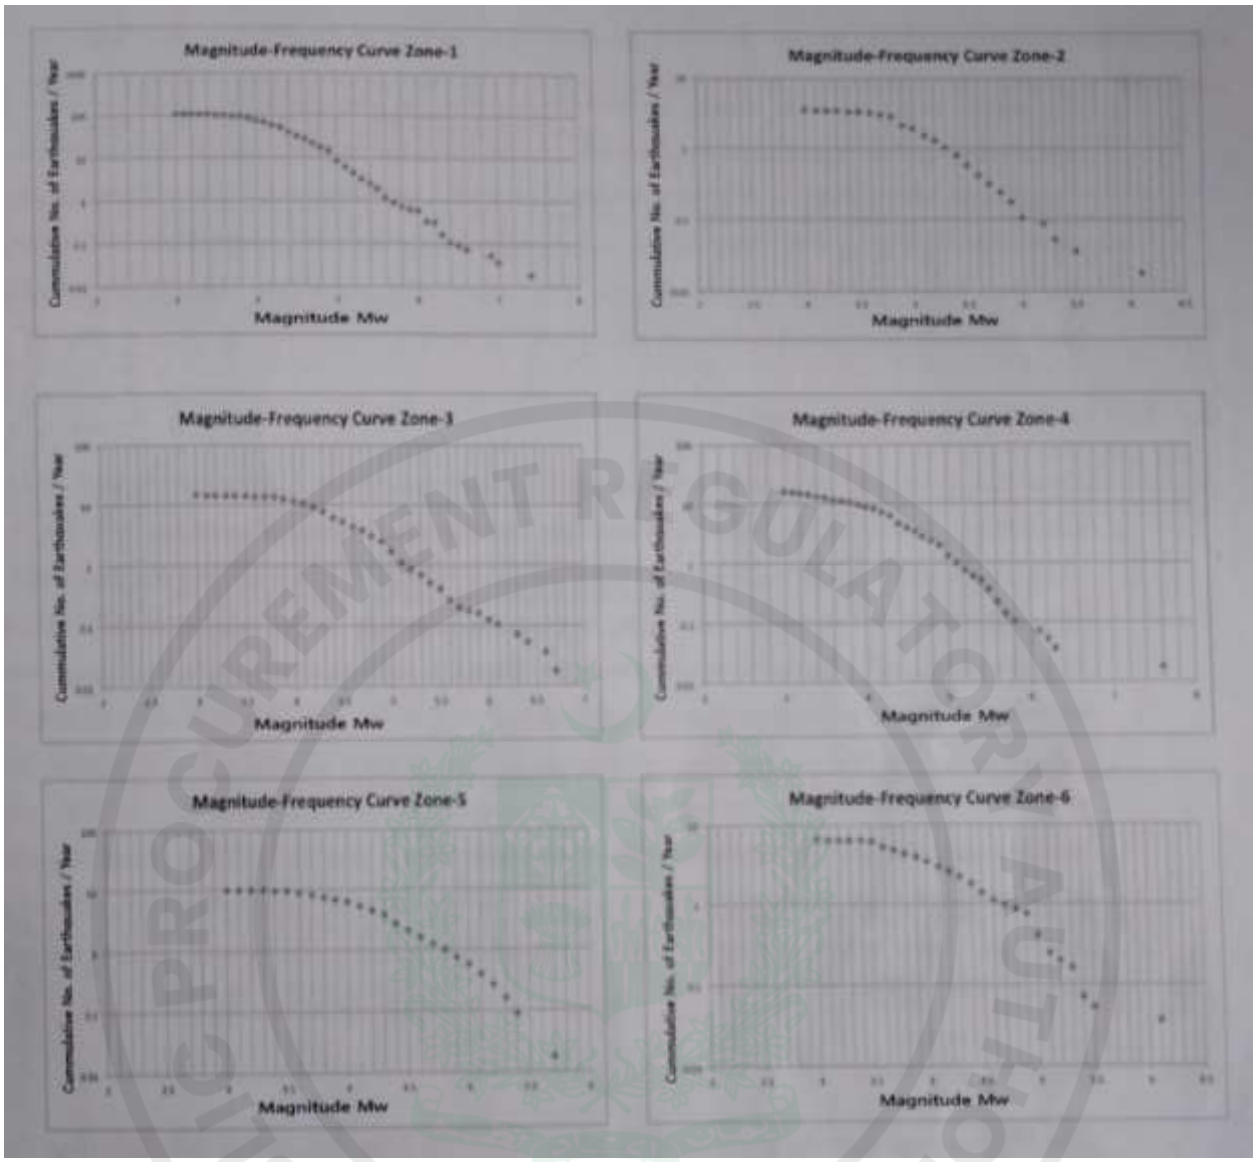

Figure 6-23 Magnitude-Frequency Curves of Seismic Sources.

6.7.3 Activity Rate of Seismic Sources

Activity rate of seismic sources have been worked out using Ez-Frisk software and the results of the analysis are shown in Figure 6-24.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

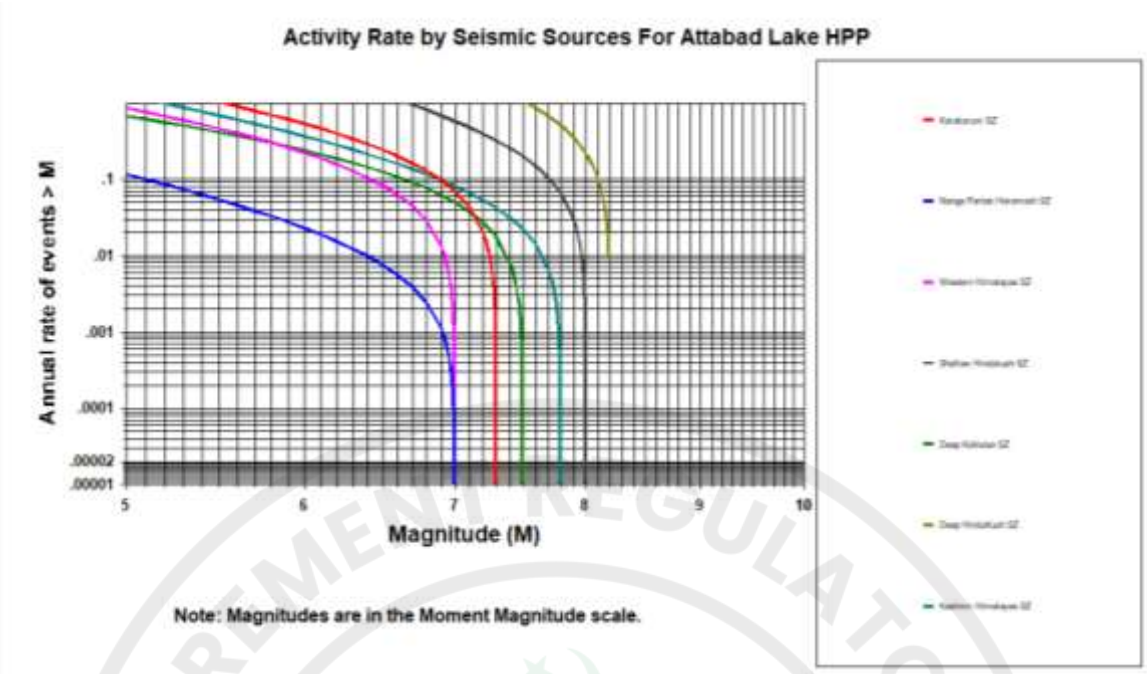

Figure 6-24 Activity Rate by Seismic Sources for ALHPP Area.

6.7.4 Maximum Magnitude

To each seismic source zone, a maximum magnitude potential was assigned based on the maximum observed seismicity in the historical seismic record and enhancing by 0.5 magnitude the maximum observed magnitude in the instrumental seismic record for that area seismic source zone and also determining the maximum magnitude of the longest active fault in the area using Well & Coppersmith equation (1994). The maximum potential magnitude used for each seismic area source zone is given in Table 6-1 and 6-2.

6.7.5 Ground Motion Prediction Equations

A number of ground motion prediction equations have been developed from strong motion database collected by USGS and Pacific Earthquake Engineering Research (PEER) Centre, USA. The latest ground motion prediction equations developed by PEER well known as Standard Five Sets of Next Generation Attenuations (NGA) West 2 have been used in the present analysis for ALHPP.

6.7.6 Seismic Sources Modeling

On the basis of tectonic, geologic and seismic characteristics, the following area source models within a radial distance of 200 km have been worked out and the same have been used as input parameters in PSHA for ALHPP.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 6-2 Seismic Source Zones Parameters for PSHA

Source Zone No.	Seismic Source Zone Name	Minimum Magnitude Mw	Activity Rate / Year	b-Value	Maximum Magnitude Mw
1	Karakorum Seismic Zone	4.0	1.929	1.120	7.3
2	Nanga Parbat Seismic Zone	4.2	1.112	1.101	7.0
3	Western Himayan Seismic Zone	4.1	5.339	1.44	7.0
4	Hindukush Seismic Zone	4.2	59.107	1.20	8.0
5	Kashmir Himalaya SZ	4.2	7.143	1.13	7.8
6	Kohistan SZ	4.1	10.500	1.07	7.5

Each of these area sources were assigned a maximum magnitude based on recorded seismicity and potential of the faults within the zone and a minimum magnitude based on threshold magnitude observed in the magnitude-frequency curve for the source zones (Figure - 23). As the shallow earthquakes are of more concern to seismic hazard, the minimum depth of the earthquakes is taken as 5 km for all area sources.

The source zone parameters used in deterministic approach is given in Table 6 - 1 and seismic sources parameters for PSHA for the ALHPP are presented in Table 6 - 2.

As the description of all these area seismic sources is found in already published literatures, therefore, their repetition has been avoided here for the sack of conciseness and brevity of the report.

6.8 RESULTS OF PROBABILISTIC HAZARD ANALYSIS

Both PSHA and DSHA were carried out using EZ-FRISK software Version 7.65 developed by Risk Engineering Inc. USA. The latest version of R-CRISIS Software Version 21.1.1 developed by PEER, USA was also used during the current study. The purpose of using both softwares was to cross check the validation comparing the quality of the seismic hazard analysis of the two software for the Project. During the study it was found that Ez-Frisk software is more standardized as compared to R-CRISIS software in quality of analysis as well as the smart outputs of the analyzed results. Therefore, Ez-Frisk software has been preferred and used in the in the final analysis.

Important input parameters used in probabilistic approach are presented in Table - 2. It is assumed that weir/dam foundation will mainly be placed on gravelly soil (alluvium), therefore, the site condition was taken as gravelly soil with average shear wave velocity at 30 meters

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

depth (V_{s30}) of 450 m/sec for soil site (alluvium) and 760 m/s for rock sites. The mean total hazard curve was obtained by giving equal weighting to all the Five NGA W2 Ground Motion Prediction Equations. The analyzed results of PSHA are presented in Figures 6-23 to 6-27.

The total hazard curve obtained for the Project Area is shown as Figure - 25 and the total mean Hazard Spectra showing combination of all used Ground Motion Prediction Equations for ALHPP is presented as Figure 6-26.

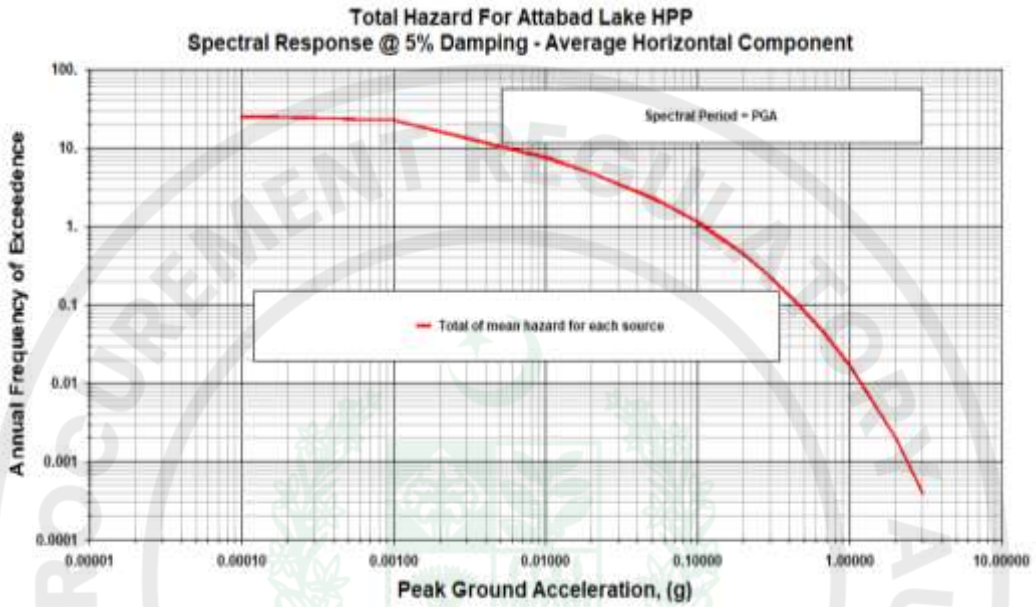

Figure 6-25 Total Hazard Curve for ALHPP

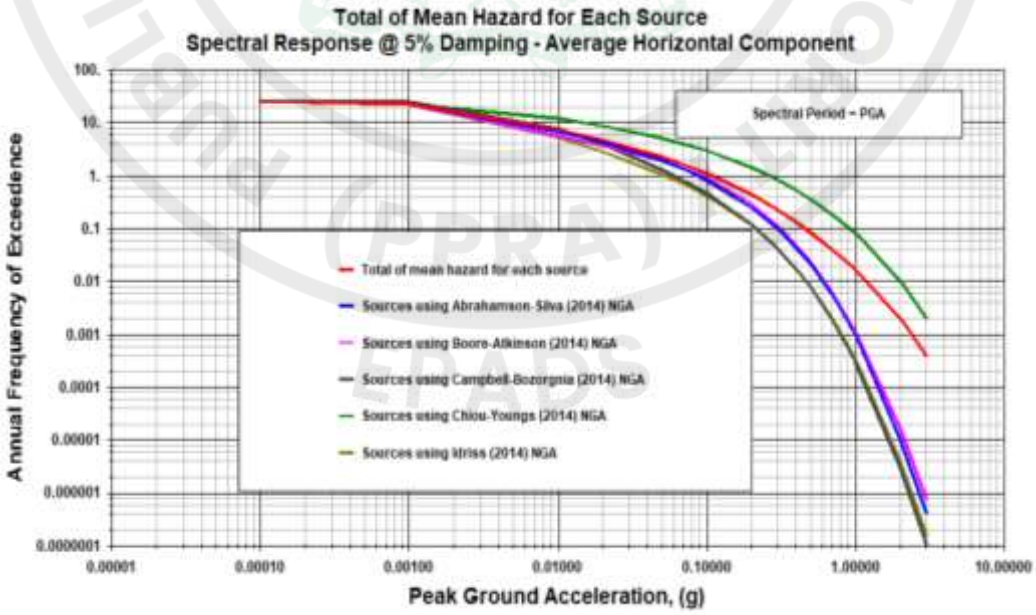

Figure 6-26 Total Hazard Spectra for ALHPP.

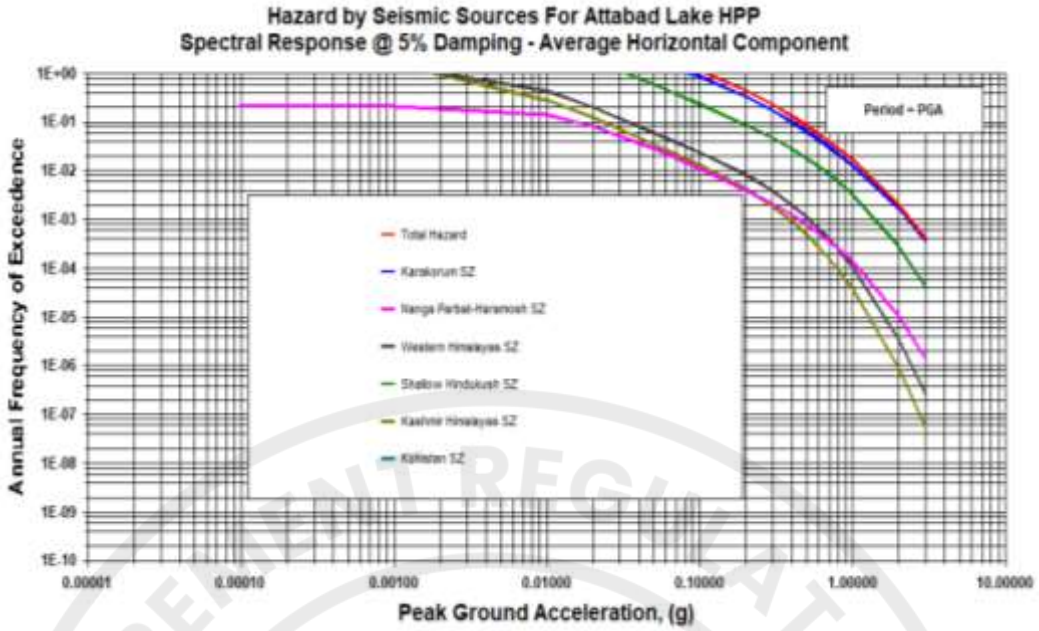

Figure 6-27 Hazard by Seismic Sources Contribution, Spectral Response @ 5% Damping for Average Horizontal Component for ALHPP..

6.9 DETERMINISTIC SEISMIC HAZARD ANALYSIS (DSHA)

The capability of the faults to generate earthquakes is ascertained by means of analysis of historical and instrumental seismic data and geological criteria such as rupture length – magnitude relationship or fault movement – magnitude relationship.

The main tectonic features around the Project Site within a radius of 200 km which could be controlling the maximum earthquake hazard are as follows:

1 Hunza Fault
2 Main Karakoram Thrust (MKT),
3 Main Mantle Thrust (MMT)

Empirical correlations have been developed between maximum potential of a fault and key fault parameters like rupture length, fault area, fault displacement and slip rate. Out of these fault parameters, only fault lengths are known with sufficient accuracy. For the faults around the ALHPP Site, the half rupture length of the faults has been taken for determination of maximum potential magnitude. The maximum earthquake magnitude (in moment magnitude M_W) of each of the fault was calculated using Wells & Coppersmith (1994) relationship between fault rupture length and magnitude and the input data given in Table - 1 has been used for deterministic approach.

Ground motion prediction equations developed under the Next Generation Attenuation (NGA) West 2 Project of PEER (Pacific Earthquake Engineering Research Center, University of California at Berkeley, USA) are used to obtain the median and median plus-one percentile levels of peak horizontal ground acceleration (PGA) in deterministic approach.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The NGA equations are developed using a large worldwide database of strong motion recording of earthquakes of magnitude 4-8 and distances ranging from 0-200 km in accordance with ICOLD Guidelines. The NGA equations are preferable over the older equations for the evaluation of seismic hazard particularly in the near field as these are based on a broad spectrum of data recorded in the near field. The same attenuation equations were used for the PSHA approach too.

For all the seismic sources, thrust rupture mechanism has been considered. It is assumed that dam foundation will mainly be placed on gravelly soil therefore the site condition for dam/weir was taken as gravelly soil with average shear wave velocity for top 30 meters (V_{s30}) of 760 m/sec. The depth to basement rocks (Z_{25}) is taken as 5 km. The PGA g values have been calculated using the latest Five sets of NGA West 2 Ground Motion Prediction Equations (GMPEs).

Input values in DSHA are given in Table - 1. The analyzed results obtained through DSHA are presented in Figures 6-28 to 6-30.

6.9.1 DETERMINISTIC RESPONSE SPECTRA

Deterministic response spectra for SEE at 50th percentile and 84th percentile levels are shown in Figure - 28 and Figure - 29 respectively.

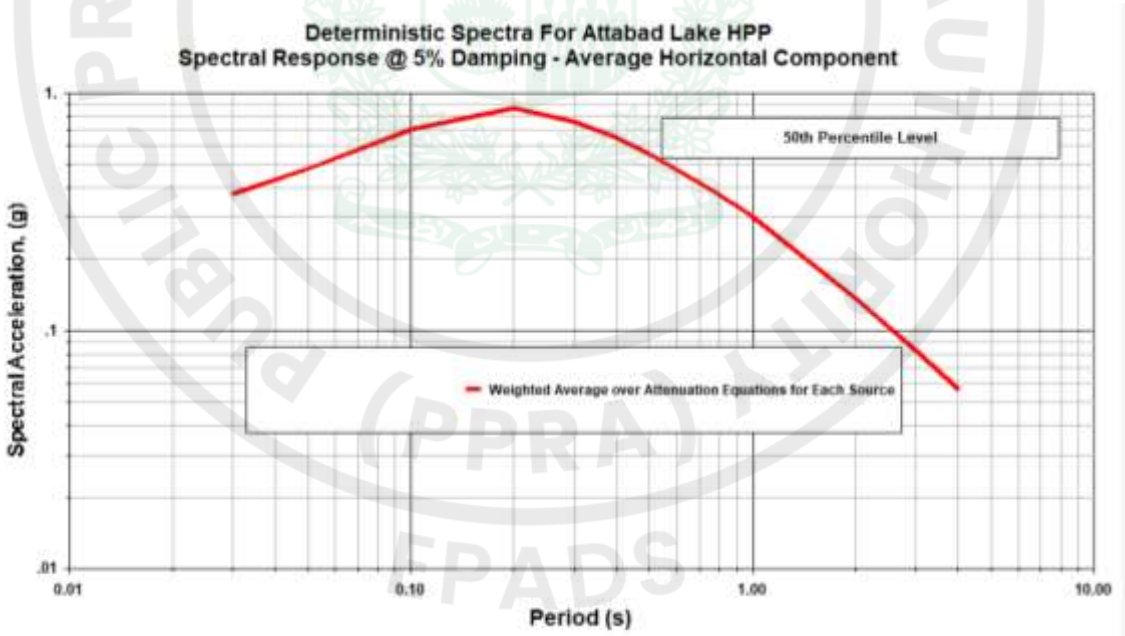

Figure 6-28 Deterministic Spectra at 50th Percentile Level

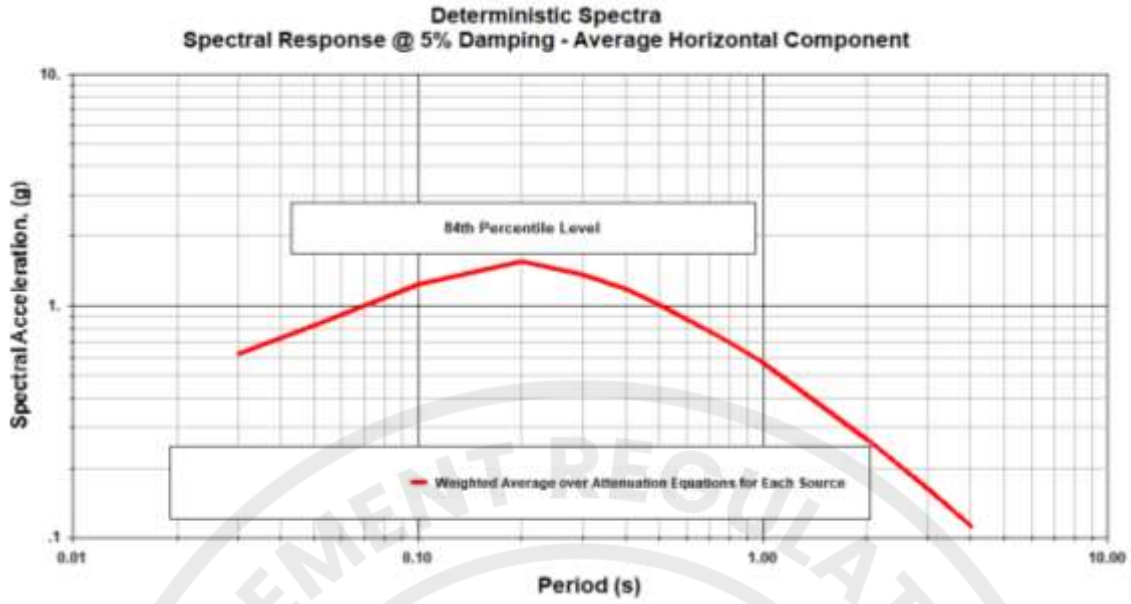

Figure 6-29 Deterministic Spectra at 84th Percentile Level.

6.9.2 Deterministic Pseudo Spectral Acceleration (PSA)

Pseudo spectral acceleration has been worked out using the latest version of R-CRISIS software. Pseudo spectral acceleration Vs time is given in Figure 6-30.

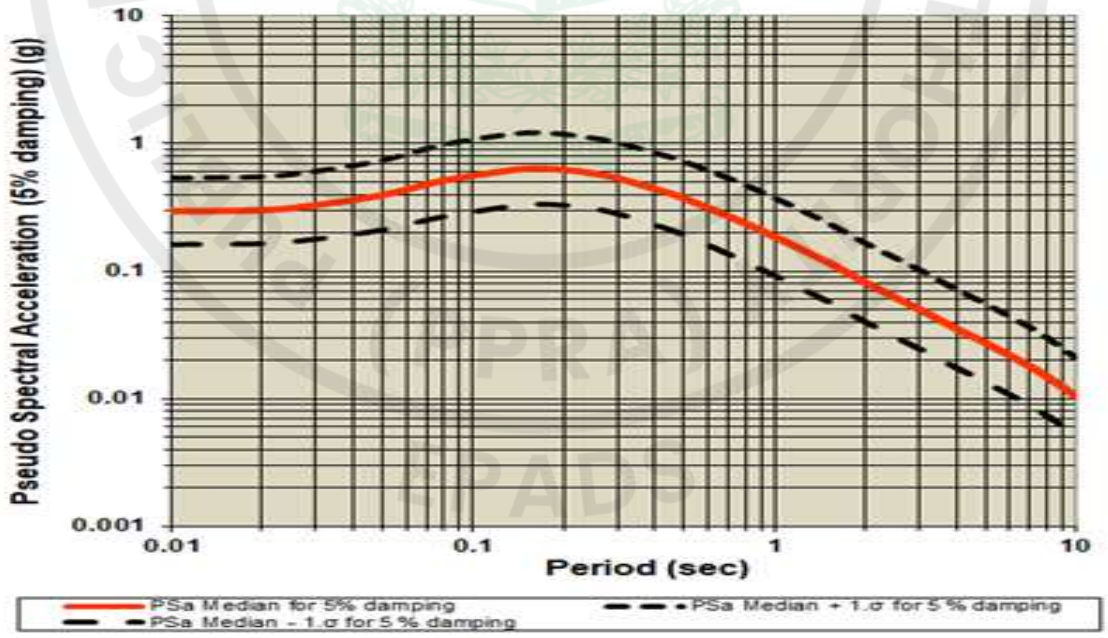

Figure 6-30 Deterministic Pseudo Spectral Acceleration (g) at 5% Damping.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6.10 SELECTION OF SEISMIC DESIGN PARAMETERS

6.10.1 Safety Evaluation Earthquake (SEE)

As per ICOLD guidelines, (2016) the SEE will produce the maximum level of ground motion for which the dam should be designed or analyzed. For dams whose failure would present a great social hazard, the SEE will normally be characterized by a level of motion equal to that expected at the dam site from the occurrence of deterministically evaluated MCE or of the probabilistically-evaluated SEE earthquake ground motion with a very long return period, for example 10,000 years for high consequence large dams. Depending on the circumstances (e.g. the importance of the dam, the consequences of a dam failure, it is recommended to design safety-critical elements such as the bottom outlet and/or spillway gates for the SEE. It will be required at least that there is no uncontrolled release of water when the dam is subjected to the seismic load imposed by the SEE.

As per the latest ICOLD Guidelines, for medium consequence dams, median value (50^{th} percentile level) is recommended whereas for high consequence dams, the SEE ground motion parameters should be estimated at median plus one (84^{th} percentile level) if developed by a deterministic approach and need not have a mean annual exceedance probability (AEP) smaller than 1/10,000 if developed by a probabilistic approach. For a particular project of importance such as hydropower project, optimum percentile level may be any optimum percentile level between 50^{th} percentile level to 95^{th} percentile level. For ALHPP, 66^{th} percentile level has been worked out and the same is recommended.

The worked out SEE for ALHPP are given in Figures 6-31.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

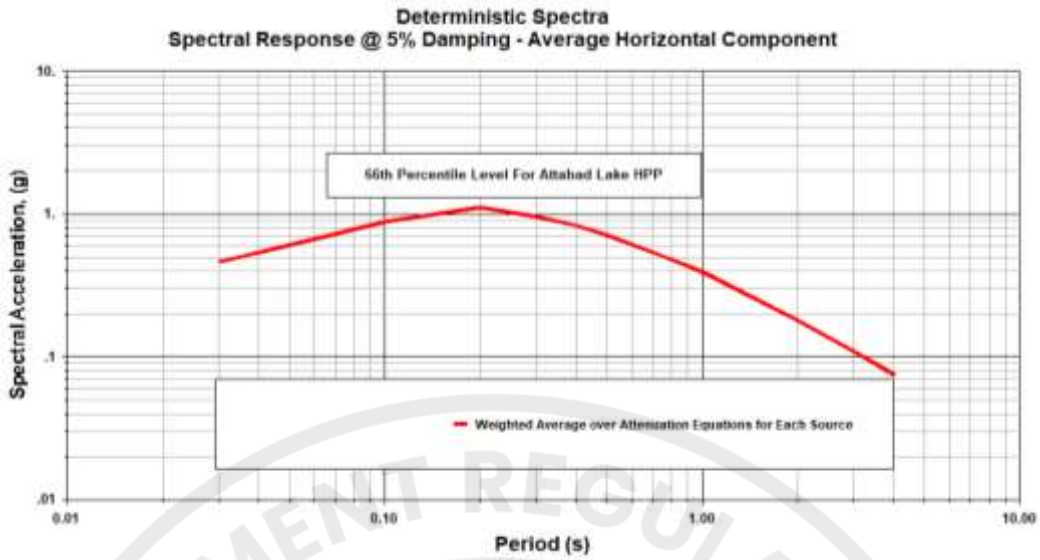

Figure 6 -31 Deterministic Spectra at 66th Percentile Level of SEE, Weighted Average over the Five NGA West 2 Equations for ALHPP.

6.10.2 Operating Basis Earthquake (OBE)

The OBE represents the level of ground motion at the dam site at which only minor damage is acceptable. In theory the OBE can be determined from an economic analysis, but this is not always feasible and, in many cases, it will be appropriate to choose a return period of about 145 years (i.e. a 50 % probability of not being exceeded in 100 years). The dam, appurtenant structures and equipment should remain functional and damage easily repairable, from the occurrence of earthquake shaking not exceeding the OBE.

Since the consequences of exceeding the OBE are normally economic, the circumstances in a particular case may justify use of a more severe or less severe event for the OBE. The resulting return period depends on prevailing conditions.

Because of the above definition, the OBE is the best determined by using probabilistic procedure. OBE ground motions are significantly lower than those for SEE.

6.10.3 Uniform Hazard Spectra (UHS)

Uniform hazard spectra for ALHPP for OBE (145 year return period), DBE (475 year and 2475 years return period) and SEE (10,000-years return period) are presented as Figure 6-32.

7 CONCLUSION AND RECOMMENDATIONS

Based on the analysis results, the following earthquakes design parameters are concluded and recommended for ALHPP.

7.1 Operation Basis Earthquakes (OBE):

OBE at return period of 145 years is recommended as follows:

OBE Horizontal = 0.24 g

OBE Vertical = 0.17 g

7.2 Safety Evaluation Earthquakes (SEE):

For the design of dam / weir, the following PGA ‘g’ values for SEE are recommended:

SEE Horizontal = 0.44g

SEE Vertical = 0.29g

For the design of appurtinent structures including spillway etc. the following PGA ‘g’ values for SEE are recommended:

SEE Horizontal = 0.38g

SEE Vertical = 0.26g

1 INTRODUCTION

1.1 GENERAL

Gilgit-Baltistan, formerly part of the Northern Areas, is the northern most administrative territory of Pakistan. Gilgit-Baltistan lies at the extreme north of the country with borders joining Xinjiang Province of China in the north, Chitral in the west and Kalam, Kohistan and Kaghan valleys in the south. Towards the east are the Indian occupied territories of Ladakh and Kashmir. Gilgit-Baltistan is linked via the Silk Route: i.e. the Karakoram Highway which starts from Mansehra district of Khyber Pakhtunkhwa and ends at the Khunjerab Pass of Hunza District where the road continues into China.

Administratively, the Gilgit-Baltistan is divided into 10 districts: Gilgit, Ghizer, Hunza, Nagar, Skardu, Ghanche, Shigar, Kharmang, Diamer and Astore. Previously there were seven districts in the region. In 2016, the number rose from seven to ten after the addition of 2 districts in Baltistan region and the bifurcation of the Hunza-Nagar district. As of 2021, there are 10 districts in the entire region, four in the Baltistan Division, four in the Gilgit Division and two in the Diamer Division. In 2019, Darel, Tangir, Gupis–Yasin and Roundu were announced as new districts by the GB Cabinet, but so far these districts are not notified officially.

Figure 1-1: District and Tehsil Boundaries of GB

Tourism in Pakistan is a growing rapidly. One renowned travel guide book termed Pakistan "tourism's next big thing". Pakistan was also ranked “the best holiday destination for 2020” and

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

was also declared the third-highest potential adventure destination in the world for 2020 by a travel magazine.

Gilgit-Baltistan is home to five of the "eight-thousanders" out of fourteen and to more than fifty peaks above 7,000 meters (23,000 ft). The region is home to some of the world's highest mountain ranges. The main ranges are the Karakoram and the western Himalayas. The Pamir Mountains lies at the north, and the Hindu Kush lies to the west. Amongst the highest mountains are World's 2nd highest peak 'K2' (Mount Godwin-Austen) and World's 9th highest peak 'Nanga Parbat'. Three of the world's longest glaciers outside the polar regions are located in Gilgit-Baltistan: the Biafo Glacier, the Baltoro Glacier, and the Batura Glacier. There are, in addition, several high-altitude lakes in Gilgit-Baltistan

Hunza Valley was composed of two independent kingdoms: Hunza and Nager in the early 1600s. Hunza is located on the branch of the ancient Silk Route from Kashgar to Kashmir and is linked to Turkistan/western China since ancient times.

Hunza is one of the primary destinations in Pakistan and is the center piece of tourism in the northern region. The major valleys in Hunza are Nilt, Nagar, Shimshal, Morkhun, Chapursan and Hanging Glacier in high Karakoram Range. The climate varies widely from monsoon-influenced moist temperate to arid and semi-arid cold deserts in the north. Below 3000 m.a.s.l, precipitation is less than 200 mm per annum while there is a sharp precipitation gradient along the altitude, and over 2,000 mm annual snow fall above 6000 m.a.s.l. Climate of the area is cold arid with moderate dry summers and severe winters.

Figure 1-2: Affected Area of Attabad Village

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Attabad Lake was created due to a massive land slide in January, 2010. Water and Power Department of Gilgit Baltistan intends to utilize this storage as an opportunity to develop Hydropower Project of appropriate capacity utilizing this potential in order to meet the ever increasing demand of Hunza district and its suburbs.

1.2 LOCATION

The Attabad Lake HPP is located in the Gilgit-Baltistan. The site of the project is located on Hunza River at Attabad Lake about 15 km upstream from Ganish Bridge of Hunza. Its distance is about 20 km from Hunza, 115 km from Gilgit. The powerhouse location is on the left bank of river and easily accessible from Karakoram Highway. The intake weir/dam site is selected at current exit point of Attabad Lake which was formed in the year 2010 due to a huge slide from right bank mountain.

The Hunza River is joined by several tributaries like Chapursan, Khunjerab, Ghujerab, Shimshal and Hisper Rivers. Nagar is the nearest district to Hunza and its capital is 25 km from the project site.

1.3 ENVIRONMENTAL AND SOCIAL IMPACT ASSESSMENT (ESIA)

The ESIA is the planning tool developed in recent years to foresee the environmental and social impacts of human intervention in nature arising from development projects. Major hydropower and storage dam projects invariably result in many far-reaching environmental, ecological and socio-cultural changes. Some of these changes benefit human population, while others threaten the natural resource base on a short or long term basis.

The undesirable changes are not solely restricted to increasing pollution or loss of natural resources and habitats for native flora and fauna, but they cover the entire range of environmental and social components, such as soil, water, air, and socio-economic and cultural system. It is now accepted fact that for sustainable economic development, strategies must be compatible with environmental goals. This requires the incorporation of environmental consideration into the process of development. It is important to make choices and decisions that will eventually promote sound development by understanding the environmental functions under the exercise of power conferred by Section 33 of PEPA, 1997, EPA, Pakistan with the approval of the Federal Cabinet has promulgated EPA Regulations, 2000. These regulations provide the basis for the screening of a Project as per Project size and magnitude. The subject Project falls under the Schedule II of category E, which is related to Water Management, Dams, Irrigation and Flood Protection with criteria that dams and reservoir with storage volume of 50 Mm^3 and above or surface area greater than 8 km^2 and hydro projects above 50 MW of installed capacity requires an EIA. Attabad Lake Hydropower Project has installed capacity of 54 MW having reservoir surface area of 4.5 km^2, therefore, it requires an EIA for the issuance of NOC from the concerned EPA.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The negative environmental and social impacts of a development project are avoided or minimized through the ESIA and where adverse impacts cannot be avoided, the mitigation measures and resettlement activities are conceived and executed as part of the project.

The overall objectives of an Environmental and Social Impact Assessment in accordance with the Pakistan Environment Protection Act (PEPA 1997), and the World Bank guidelines (OP 4.0) include the following:

- Help ensure the environmental and social soundness and sustainability of projects.
- Support integration of environmental and social aspects of projects into the decision making process.
- Promote environmentally sustainable development by supporting the protection, conservation, maintenance, and rehabilitation of natural habitats and their functions
- Avoid or minimize involuntary resettlement and if not feasible, to assist displaced persons in improving or at least restoring their livelihoods and standards of living in real terms relative to pre-displacement levels or to levels prevailing prior to the beginning of project implementation, whichever is higher.
- Design and implement projects in a way that fosters full respect for indigenous peoples' dignity, human rights, and cultural uniqueness and so that they: (a) receive culturally compatible social and economic benefits; and (b) do not suffer adverse effects during the development process.
- Assist in preserving physical cultural resources and avoiding their destruction or damage.
- Assure quality, health and safety in the design and construction of new dams and the rehabilitation of existing dams, and in carrying out activities that may be affected by an existing dam.
- Enable vulnerable and disadvantaged stakeholder groups to participate in an informed manner.

1.4 PROJECT CATEGORIZATION

According to Pakistan Environment Protection Agency regulations for review of IEE and EIA, hydroelectric projects with a generation capacity of over 50 MW and power transmission lines with a capacity more than 11 kV fall into Schedule-II, i.e. projects requiring EIA. Similarly, in accordance with the guidelines of the World Bank, the Asian Development Bank and the Japan Bank for International Cooperation Environmental guidelines, the Attabad Lake HPP (with a planned generating capacity of 54 MW and 132 kV power transmission lines) would fall within the category 'A' projects could be having significant impacts on the environment and requiring a full scale EIA.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

1.5 SCOPE AND LIMITATIONS OF ESIA

1.5.1 Scope

The scope of the study proposed by WAPDA in the Terms of Reference (TOR) for this feasibility study includes this ESIA which only covers the dam site, reservoir, powerhouse areas and transmission systems. Resettlement Action Plan (RAP) is not under consideration as there is no displacement of people involved. Team of Engineers from Hydro planning have envisaged the following Statement of Work related to environmental studies:

a. Review of national and local guidelines, laws and policies;
b. Review of all relevant existing data, studies, reports and drawings;
c. Avoid, minimize, mitigate and the potential significant environmental and social impacts due to the proposed intervention;
d. Collection of baseline data related to Physical, Ecological and Social environmental aspects;
e. Identification, evaluation and categorization of the potentially significant adverse physical, ecological and socio-economic impacts on the local environment during the construction and operational stages of the proposed Hydropower Project;
f. Recommend appropriate environmental and social mitigation measures for the identified adverse impacts and monitoring plans to address them;
g. Preparation of Environment Monitoring Management Plan (EMMP);
h. Cost estimate for environmental setup;
i. Public consultation and disclosure;

1.5.2 Limitations

The baseline information documented in the present report reflects the prevailing physical, biological and socio-economic conditions of the project area. The project is at feasibility stage and the detailed design and tender documents preparation stages will follow during the execution. If the project is implemented after two years of completion of the feasibility stage then certain variables such as development of infrastructure, population growth, increase or decrease in the forest, land use, cropping patterns and economic conditions could be changed significantly.

1.6 APPROACH AND METHODOLOGY

1.6.1 Review of Previous Studies

Attabad Lake Hydropower Project was conceived by Water and Power Department, Govt. of GB for 32.5 MW. Consequently, a Feasibility Study was conducted by the Water & Power Department Gilgit Baltistan through Consultants. No detailed EIA was required for less than 50 MW installed capacity. Only Initial Environmental Examination was carried out to fulfill the requirement of the Pakistan Environmental Protection Agency (PEPA) by the consultants engaged by Govt. of GB. Later on the request of Govt. of GB, WAPDA updated the feasibility study of the project with

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

enhanced capacity of 54 MW and for such project, detailed environmental and social impact assessment study was required.

The following earlier project reports have been reviewed to assess their applicability in the prevailing environmental conditions specially in Gilgit Baltistan region:

- Bunji Hydropower Project: Feasibility Study Report (Vol-III), Environmental Impact Assessment by Bunji Hydropower Consultants (March 2005).
- Detailed Engineering Design Report of Phander Hydropower Project.
- Feasibility Study Report of Shyok Dam Project, Environmental Impact Assessment Study.
- And Various Other Reports Related to Gilgit Baltistan.

1.6.2 Acquisition of Secondary Data

The secondary data was collected from various offices and published reports of different organizations in the Gilgit Baltistan. These organizations included Water & Power, Education, Forest, Agriculture, Fisheries, Sanitation, Wildlife, Environmental Protection Agency, District Administration, Tehsil Offices, Local Councils and others. The studies are carried out on the information received during field visits of Project area, data received from some NGOs, water samples collected from project area at various places and tested in Gilgit-Baltistan Environmental Protection Agency Laboratory, Gilgit, climate data received from Metrological department, and other data taken from earlier conducted feasibility study and other reports of projects.

1.6.3 Collection of Primary Data

The primary data were collected and assessed with reference to different project components, i.e. dam site, reservoir area, powerhouse, construction camps etc. The data regarding climate, hydrology, geology, seismology, neo-tectonics and other physical features of the project area were also obtained as part of the preparation of this feasibility study. Data collected from the villages as shown in the Figure1-3

i. Vegetation Studies

The assessment area for terrestrial flora and fauna encompasses the terrestrial environments upstream and downstream of the dam and adjacent areas that may be affected by the project activities, specifically from the dam to the upper end of the reservoir impoundment and from the dam to the powerhouse.

Since the lake was formed in January 2010 and no new area would be submerged with the project except the powerhouse site, therefore, there would be no new threat to plants with the construction of hydropower project. However, concentration was given to study the rare species and special emphasis was given to the economic species such as medicinal plants.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

ii. Wildlife Fauna Studies

Information on wildlife fauna species (mammals, amphibians, reptiles, birds etc.) in the assessment area was compiled based on opportunistic observation, gathering the existing information and consultation with local experts, community members and government and non-government organizations.

iii. Aquatic Ecology

Generally Northern Area are blessed with great water resources comprised of rivers, streams, and alpine lakes fed by the snowmelt and glacier waters. These freshwater resources harbor several fish species, which are the important component of the biological diversity. The fish fauna in Hunza Valley is relatively poor due to high turbidity, low water temperature and high water speed.

iv. Environmental Flow Study

An environmental flow study was carried out to determine the optimum environmental flow downstream of the proposed dam for sustainability of the aquatic ecosystem. The study is based on the hydrological data 50 years obtain from Surface Water Hydrology Department WAPDA that involves analysis of river flow data coupled with aquatic ecosystem analysis.

v. Social Surveys

The purpose of social survey was to record the present conditions of the people living in the project area and to assess the expected project impacts on their life, subsistence systems, and social and cultural conditions. Prior to conducting the field surveys, the following steps were taken:

- Geographic boundaries of the project area were identified and existing villages and settlements were listed.
- Decided the sampling procedure in order to draw a representative sample size of the target population and households
- Developed the tools for data collection i.e. questionnaires for household sample survey, village profile, women sample survey, community participation and water use.

In order to obtain comprehensive and detailed information, the following techniques and tools of data collection were used.

vi. Sampling Design

A stratified proportionate random sampling technique was applied to select adequate and representative samples to generalize survey findings at the project level. The stratification variables were taken into consideration for enhancing the representation level for adopting appropriate sampling design.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

vii. Stratification Variables

The major objective of the study was to establish baseline socio-economic conditions for the inhabitants near the existing reservoir upto original extent of lake formed in 2010, powerhouse and adjacent areas of the project. The following factors were taken into consideration for enhancing the probability of every household being selected in the sample size:

Each village was included in the sampling frame because of the heterogeneity of socio-economic characteristics between villages and relatively homogeneity within a village.

viii. Sampling Unit

The primary sampling unit for the socio-economic survey was the head (male or female) of the household falling within the nine sample villages of proposed Attabad Lake Project area.

ix. Basic Unit of Study

The basic unit of study and analysis for the purpose of socio-economic investigation is nine villages of project area for Attabad Lake Hydropower Project.

x. Questionnaires

In order to test the validity and reliability of the proposed questionnaires, interviewing guides were pre-tested in the area and then the questionnaires were reviewed to assess whether questions needed to be clarified, changed or re-sequenced and then a final editing of questionnaires was conducted prior to their subsequent application in the real sample areas.

List of Respondents of socio-economic survey is attached at **Appendix-A** The different questionnaires used for the social survey are included in **Appendix-B** of this volume.

xi. Field Investigators

A team of experts of Hydro Planning Organization moved to project area for field investigations. The team hired services of one local graduate lady and one local graduate man for questioning and answering with local people in their language. The team spent more than three weeks to visit seven villages of upstream and two villages of downstream side of the project area. In this exercise both genders were covered in field visits of project area. The role playing exercises provided the field investigators with the ability and confidence to establish a rapport with the respondents as well as other interviewing skills in order to minimize the no sampling error, wrongly asked or interpreted or recorded answers. The services of a local well educated female were hired for the data collection on the subjects of gender and women empowerment.

xii. Interviewing Guide for Community Participation

Well informed persons in the village were interviewed by using a questionnaire to obtain information about village and their perceptions about the project.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

xiii. Household Sample Survey

Household heads of total sample size from each sample village of the project area were interviewed by using structured questionnaires. Detailed information about the socio-economic status of the family and household was obtained from the respondents.

xiv. Village Profile

A comprehensive village profile was prepared to document the socio-economic and demographic data of each sample village in project area.

xv. Gender Survey

The experts developed a separate questionnaire covering various aspects and issues of women in the area. The services of a qualified local female were hired for this survey. Women from all the villages were interviewed. Respondent women were selected by applying the same technique as used for socioeconomic survey.

xvi. Data Editing

The filled-in questionnaires and interviewing guides were edited by the same field investigators, who were involved in the data collection. This was done immediately after completing the field investigations.

xvii. Data Analysis

Data sets were processed after the completion of the field survey and editing of socio-economic information. Analysis of this diversified data and preparation of conclusions in the minimum possible time was achieved using statistical techniques of data analysis.

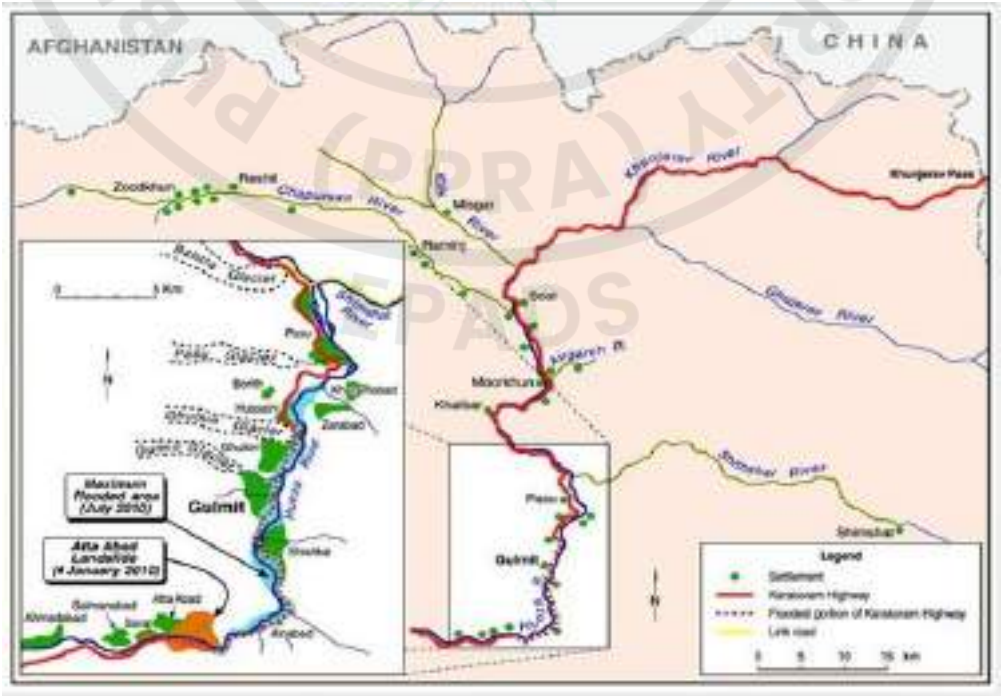

Figure 1-3: Extent of Attabad Lake showing Villages

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

2 Project Description

2.1 BACKGROUND

The Hunza region is facing acute shortage of power resulting in long hours Load Shedding in the area, especially the conditions become worse in winter season, due to low flows in streams. Presently, there is high supply and demand gap; therefore, load shedding is common in summer, while it becomes very acute in winter. The commercial and industrial demand is partly fulfilled from privately owned diesel generators. The diesel generators are mainly used by the hotels, small businesses, banks and other consumers which can afford the high running cost. Apart from the cost the use of these diesel generators is creating environmental pollution (i.e., noise and air), which is also affecting the tourism in the area. The expected fast growth in tourism industry will immensely increase the electricity demand in future, if not planned properly and addressed timely, it will most likely create a crisis like situation in the near future.

2.2 PROJECT INTRODUCTION

Attabad Lake Hydropower Project is proposed on Attabad Lake which is located on the Hunza River in the Hunza District of the Gilgit-Baltistan. Attabad Lake was created due to land slide dam formed in January, 2010 due to a huge landslide from right bank of Hunza River at Attabad about 15 kilometers upstream of Ganish Bridge and about 111 kilometers upstream of Gilgit.

The project has been sized as per flows availability, size of conveyance system and surface powerhouse executable under prevailing topographic and geological features. The plant size of 54 MW will provide the installed power during peak hours throughout the years. The off-peak power would remain from 20 to 54 MW in six winter months, while in six summer months, 54 MW would be available for 24 hours.

A weir/dam will be constructed to divert the flow of Hunza River into Head Race channel, 2300 m long nearby Karakoram Highway. Before construction of weir, a deep flushing channel/ under sluices structure would be constructed in order to lower down the level of lake and to evacuate the water from lake on the left side of existing outlet. The under sluices structure will also act as flushing of sediment from the lake once project comes into operation. The diverted water enters into the head race tunnel 2300 m long. The tunnel is followed by surge shaft. Water will enter into 450 m long penstock pipe branching into three units at the end through manifold. These high-pressure penstock pipes and feed three turbines, for the generation of 54 MW hydropower. Layout of the Project is attached at **Drawing-I**.

The project is proposed to be developed on Hunza River at Attabad Lake with design discharge 60m^3/s to generate the rated power round the year. This project will enhance the generation capacity and augment the power supply network of entire Hunza-Nagar Valleys and Gilgit Town. Once completed and operational this project will help improve the power supply situation in the region.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The salient features of the envisaged power supply project are given as follows;

- Type of Development: High Head Run of River with Peaking
- Gross Head: 111.7 m
- Net Head: 105.5 m
- Installed Capacity: 54MW
- Type of Turbine: Francis (Vertical)
- No. of Units: 03
- Design Discharge (Q_d): 60.00 m^3/s (20 m^3/s to each unit)
- Overflow Weir Length: 60 m
- No. of Undersluices: Three (03)
- Undersluice Gate Size: 5m x 5m
- Power Tunnel Length: 2300 m
- Penstock Length: 450 m
- Type of Powerhouse: External
- Annual Energy: 373.69 GWh
- Plant Factor: 79 %

2.3 PROJECT COMPONENTS

2.3.1 Civil Works

2.3.1.1 Main Weir

The weir is located on the natural spillway of Attabad Lake. It will be an overflow type weir having 60 m width. Crest of weir is located at 2414 m.a.s.l. and has been designed to pass the flood of 3,250 m^3/s along with undersluice. The existing spillway will be treated and given a proper shape of a weir. Grouting and cutoff wall will be provided to keep the structure safe from any kind of seepage.

2.3.1.2 Undersluice

The undersluice channel is provided for the diversion of flow during the execution stage and for sediment flushing during operation stage of the project. Life of Attabad Lake will be maintained by flushing the sediments during most months of the year. A rectangular shaped Undersluice channel has been proposed at an elevation of 2402 m.a.s.l having width of 20 m.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

2.3.1.3 Power Intake

The Intake will be the structure built to divert the design flow from the lake towards the headrace for onward transmission to the proposed power house. The intake would ensure proper & efficient working besides adherence to the hydrology of the River during low flows, normal flows and maximum possible flows.

Intake structure has been proposed at the point where the earthen embankment meets the face of left bank mountain in the rocks exposed on left bank just closed to lake boundary. The sill level of intake structure has been proposed as 2404 m.a.s.l. The maximum and minimum operation levels of water have been kept as 2414 m.a.s.l. and 2412 m.a.s.l. respectively. A trash rack will also be provided at the front of intake structure to avoid the entering of unwanted materials.

2.3.1.4 Low Pressure Headrace Tunnel

A horse shoe type low pressure power tunnel of 5.2 m width has been proposed on the left bank of the river with diversion intake to cater the 60 m^3/sec design discharge for the power generation. Power Tunnel having 2300 m length passes through the stable rock portion on the left side.

2.3.1.5 Surge Shaft

Surge tank has been proposed to accommodate surges to facilitate maintaining water level in headrace tunnel.

The surge shaft is proposed have an internal diameter of 8.0 m and maximum surge level reaches upto 2440 m.a.s.l.

2.3.1.6 Penstock

One penstock will be laid down at the end of power tunnel to convey flow to powerhouse. The length of the penstock is about 450 m with diameter of 3.6 m. The thickness of steel is kept as 20 mm to withstand the water pressure. The initial 80 m penstock from surge tank would be pressure tunnel.

2.3.1.7 Power House

The external type powerhouse is proposed near the old Chinese camp at 2 km downstream of existing spillway of Attabad Lake. It will be constructed in front of Sarat village near the bridge on Hunza river. It is designed for three vertical Francis units. The approximate dimensions of the power house will be L x W x H are 45 m x 18 m x 22 m. The turbine level in powerhouse has been kept as 2300 m.a.s.l., and the level for draft tube has been proposed as 2293 m.a.s.l.

2.3.1.8 Tailrace channel

Tailrace Channel consists of an open channel forming part of power house structure and connecting to river Hunza. Tailwater levels varies for different situations. For normal operation when all three units are running the tailwater level reaches upto 2302.3 m.a.s.l. and during off

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

peaking it reaches to as minimum as 2301.5 m.a.s.l. The maximum tailwater level reaches at around 2307 m.a.s.l.

2.3.2 Mechanical Works

2.3.2.1 Turbines

The installed capacity of the Attabad Lake HPP shall be 54 MW with three units each having rated turbine output of 19 MW. Based on the technical and economical consideration and range of the head, Vertical Francis turbine have been selected for the Attabad Lake HPP due to the reasons that their part load operation is stable and the efficiency is high. The Vertical Shaft Francis turbines are selected for Attabad Lake HPP.

Each turbine shall be equipped with modern digital governor consisting of solid-state programmable microprocessor system of the electric-hydraulic PID type.

2.3.2.2 Inlet Valves

Butterfly valve is suggested for Attabad Lake HPP. The valve diameter as worked out shall be 1.83 m, operated by servomotors.

2.3.2.3 Cranes

One electric overhead bridge type traveling (EOT) crane of 100-ton capacity has been proposed for unloading and handling the powerhouse equipment at the loading/erection bay. Besides, the same crane shall be used for assemblies at the loading bay and for erection of plant.

2.3.2.4 Cooling Water System

Independent closed loop system for each unit has been provided for turbine and generator coolers.

2.3.2.5 Drainage System

The drainage system shall be designed to collect the Seepage water from different floors of the powerhouse. & leakage of oil from various components.

2.3.2.6 Mechanical & Electrical Workshops

For the day-to-day maintenance jobs of the power plant, mechanical and electrical workshops along with storage areas for essential tools will be provided under the erection bay of the powerhouse.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

2.3.3 Electrical Works

2.3.3.1 Generators

Three Generators with rated output of 21.2 MVA each, rated power factor of 0.85 & rated Voltage of 11kV will be coupled with the Turbines.

2.3.3.2 Transformers

Three Unit step up Transformers be installed with Rated power of 22 MVA & Rated Voltage of 11 kV/132 kV each.

2.3.3.3 Control Panels

Digital Control panels be installed for overall control of the power house and auxiliary systems.

2.3.3.4 132 kV Transmission Lines

132 kV Transmission line of 27km (double circuit) will be constructed from Attabad Lake HPP to Aliabad. And 132 kV Transmission line of 70 km (single circuit) will be constructed from Attabad Lake HPP to Sost.

2.3.3.5 Grid Stations

132 kV switchyard will be constructed at Attabad Lake HPP.

2.3.3.6 Protections

Digital type Relays of latest version will be used for protection of turbines, generators and transformers.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

2.4 SALIENT FEATURES OF THE PROJECT

Table 2-1: Salient Features of Attabad Hydropower Project

Location	Attabad village, Hunza District, Gilgit-Baltistan of Pakistan, 130 km west of Gilgit & 740 km north- of Islamabad	Design Discharge Gross head Installed Capacity Mean Annual Energy Plant Factor	60 m^3/s 111.7 m 54 MW 373.69 GWh 79 %
River Catchment Area Mean Annual Discharge Total annual volume	Hunza 8920 km^2 209 m^3/s 6591 mill m^3	Penstock Length Diameter Thickness	1 no. Embedded 450 m 3.6 m 20 mm
Weir Crest elevation Crest length Weir height Stone Pitching length	Lateral weir 2414 m.a.s.l 60 m 2.0 m 30 m u/s and 20 m d/s	Powerhouse Size Height Type of units No. of units	External slope type 45 m x 18 m 22 m Francis 3
Attabad Lake length Lake width Lake depth	14000 m 100 m 50 to 60 m	Tailrace Turbine level Max. Flood level	20 m, concrete lined 2300 m.a.s.l 2307 m.a.s.l
Tunnel length Size Type	2300 m 5.2 m diameter Horse Shoe	Firm Power Off peak winter Peak Summer	26 MW 18 MW 54 MW
Peaking Storage Full supply level Minimum supply level Gross Storage	5 Million m^3 2414 m.a.s.l 2412 m.a.s.l 123 Million m^3	Distance up to Gilgit Transmission Line upto Voltage level Areas to be served	130 km 70 km single circuit and 27 km double circuit 132 k V Hunza-Nagar, Gilgit, and Ghizar valleys

3 REGULATORY LAWS AND THE INSTITUTIONAL FRAMEWORK

3.1 GENERAL

This chapter deals with the National Policy, Regulatory Framework related to environmental protection, preservation and environmental assessment and approval procedures.

3.2 NATIONAL POLICY FRAMEWORK

The Federal Ministry of Environment (now called the Ministry of Climate Change) was established in Pakistan in 1975 as a follow up to the Stockholm Declaration of 1972. The Ministry was instrumental in the promulgation of the Environmental Protection Ordinance of Pakistan in 1983. The National Conservation Strategy (NCS) was formulated in 1992 which provides a broad framework for addressing various environmental issues and environmental conservation in the country. The Pakistan Environmental Protection Act (PEPA) was enacted in 1997 repealing the Ordinance of 1983. The Environmental Quality Standards (NEQS) were promulgated in December 28, 1999 after the approval of the Pakistan Environmental Protection Council (PEPC). The IEE/EIA Regulations were promulgated by the Pakistan Environmental Protection Agency (under Section 12, PEPA Act of 1997) in 2000. A revised version of NEQS was enforced in 2000. The Ministry of Climate Change was created in 2010 to deal with the threats posed by global warming and for environmental protection in the country. However, after the approval of 18th amendment in 2010, the matters related to environment became a provincial subject. The role of the Federal EPA is now limited to the federal capital and matters related to environment in each province has to be dealt by their own EPAs which are made more independent having their own laws related to the protection of the environment and procedures for the issuance of NOC for the development Projects.

The National Policy Framework encompasses the environmental issues which Pakistan is currently facing, especially pollution of fresh water bodies and coastal waters, air pollution, lack of proper waste management, deforestation and degradation of forest cover, loss of biodiversity, desertification, natural calamities and climate change.

3.2.1 National Conservation Strategy, 1992

The Pakistan National Conservation Strategy (NCS) was approved by the federal cabinet in March 1992 and as such formulates the principal policy document dealing with environmental conservation issues in the country. The NCS outlines the country's primary approach towards encouraging sustainable development, conserving natural resources, and improving efficiency in the use and management of natural resources.

The NCS has 68 specific programs in 14 core areas in which policy intervention is considered crucial for the preservation of Pakistan's natural and physical environment. The core areas that are relevant in the context of the proposed Project are pollution prevention and abatement,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

restoration of rangelands, increasing energy production, conserving biodiversity, supporting forestry and plantation, and preservation of cultural heritage.

3.2.2 National Environmental Policy, 2005

The National Environment Policy while recognizing the goals and objectives of the National Conservation Strategy, National Environmental Action Plan and other existing environment related national policies, strategies and action plans, provides broad guidelines to the Federal Government Provincial Governments, Federally Administrated Territories and Local Governments for addressing environmental concerns and ensuring effective management of their environmental resources.

The main objectives of the Policy are:

a. Conservation, restoration and efficient management of the environmental resources;
b. Integration of the environmental considerations in policy making and planning process;
c. Capacity building of public sector agencies and other stakeholders at all levels for better environmental management;
d. Meeting international obligations effectively in line with the national aspirations; and
e. Creation of an atmosphere for environmental protection through mass awareness and community involvement.

3.2.3 National Forest Policy Pakistan, 2001

The goal of this policy is to foster the sustainable development of Renewable Natural Resources (RNR) of Pakistan, through maintenance and rehabilitation of these essential resources and enhancement of sustainable livelihoods of rural masses particularly women, children and other deserving groups.

The various components of the policy include the following:

a. Reducing poverty, powerlessness and unemployment;
b. Population planning in critical eco-systems;
c. Reducing the impact of socio-economic factors;
d. Providing substitutes to firewood in the mountain-woods;
e. Reducing political interferences in Forestry and Wildlife Departments;
f. Renovating and invigorating the institutions of RNR;
g. Supporting Local Governments in the sustainable development of their RNR;
h. Policies for fragile eco-systems;
i. Riverside forests;
j. Irrigated plantations;
k. Preservation of sensitive and unique forests;

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

l. Wildlife conservation;

m. Rangelands and desert eco-systems; and

n. Planting trees and fodder on farmlands.

3.2.4 National Power Policy, 2013

Then Ministry of Water and Power of the Government of Pakistan developed an ambitious power policy to support the current and future energy needs of the country. This bold strategy will set Pakistan on a trajectory of rapid economic growth and social development. Simultaneously, it will address the key challenges of the power sector in order to provide much needed relief to the citizens of Pakistan. This document will frame the broad contours of the energy policy articulating the vision for the power sector, highlighting its key challenges, setting major goals, summarizing policy principles, and highlighting the strategy devised to achieve Pakistan's aspirations.

3.2.5 National Electricity Policy, 2005

The National Electricity Policy is one of the key instruments for providing policy guidance to the Electricity Regulatory Commissions in discharge of their functions and to the Central Electricity Authority for preparation of the National Electricity Plan. The Policy aims at accelerated development of the power sector, providing supply of electricity to all areas and protecting interests of consumers and other stakeholders keeping in view availability of energy resources, technology available to exploit them, economics of generation using different resources and energy security issues. This also involves development of National Grid, development of Rural Electrification Distribution, reliability and quality of power supply to be monitored by State Electricity Commissions, measures to promote competition, exploitation of small hydro, solar, biomass and wind resources / opportunities for additional power generation, emphasis on achieving higher efficiency levels through renovation and modernization, speedy implementation of stringent measures against theft of electricity, full emphasis on augmentation of R&D base and appointing Ombudsman for redressed of consumers grievances among various others.

3.2.6 Federal Government Institutions

The Federal Ministry of Climate Change deals with the issues of environmental preservation and climate change at the federal level. Within the Ministry, the NCS Resource Center (RC) is responsible for using the Information and Communication Technologies (ICTs) by setting up a decision support system in the field of environment. In addition to serving as an information and knowledge repository for all stakeholders of environmental protection and sustainable development in the country, it also aims to co-relate / restore environmental information / data, Project EIA reports, research publications, grey literature and documentaries to create accessibility among all the stakeholders, especially the public-sector agencies. This data base also contributes and facilitates decision making in the sectors of industry, health, energy, physical communication and tourism etc.

The Pakistan Environmental Protection Council (PEPC) and the PAK-EPA were primarily responsible for administering the provisions of PEPA 1997. The PEPC oversees the functioning

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

of PAK-EPA. Its members include representatives of the Federal Govt. industry and Non-Governmental Organizations (NGOs).

The Pakistan Environmental Protection Agency (PAK-EPA) was required to ensure compliance with the NEQS, establish monitoring and evaluation system, and identify the need as well as initiate necessary legislation whenever required.

PAK-EPA has delegated powers to its provincial counterparts for environmental monitoring and enforcement. One of the functions delegated by the PAK-EPA to the provincial EPAs is the review and approval of environmental assessment reports (EIA's) and the issuance of No Objection Certificates (NOCs).

3.2.7 Pakistan Environmental Protection Agency (Review of IEE/EIA) Regulations 2000

These regulations / schedules present the policy and procedures for the filing / review and approval of environmental assessment reports. The Projects falling under Schedule-I of these regulations require an IEE Report while Projects falling under Schedule-II require an EIA for the issuance of NOC by the concerned agency prior to the construction of the Project.

According to the PAK-EPA Regulations 2000 for Review of IEE and EIA, the proposed Attabad HPP falls under Schedule-II Projects, (water management, dams, irrigation and flood protection). Therefore, this EIA study was carried out for the Attabad HPP. The IEE / EIA regulations 2000 stipulate that within ten (10) working days of the IEE or EIA having been submitted, the federal/provincial agency will confirm that the document submitted is complete for the purpose of review. During this time, should the agency require the proponent to submit additional information, it will return the IEE or EIA to the proponent for revision, clearly listing those aspects that need further discussion. Subsequently, the Federal EPA / concerned Provincial EPA would make every effort to complete an IEE review within forty-five (45) days and an EIA review within ninety (90) days of filing.

3.2.8 Functions of Federal Environmental Protection Agency (PAK EPA)

The functions and responsibilities of the Pak EPA is now restricted to the only for Federal Capital and it adjoin areas. The functions and responsibilities of the Pak EPA are as follows:

a. Implement and administer the Pakistan Environmental Protection Act (PEPA)-1997;
b. Adopt effective measures for implementation of national environmental policies;
c. Enforcement of the NEQS;
d. Publish annual report on status of national environment;
e. Promote research in science and technology which may contribute to the prevention of pollution and protection of environment;
f. Promote public awareness and education in the environment sector;
g. Pak EPA can inquire or investigate any environmental issue at its own or upon complaint from any person or community.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.2.9 Functions of Provincial EPAs

a) The EPAs can advise the potential proponent(s) for taking up environment assessment studies according to Schedule I and II of the PEPA 1997;

b) Issuance of NOC for an Initial Environmental Examination (IEE) or Environmental Impact Assessment (EIA).

c) The EPA can impose penalties on the violators of the applicable laws / environmental polluters;

d) The Provincial EPA can inquire or investigate any environmental issue at its own or upon complaint from any person or community within its jurisdiction.

PUBLIC PROCUREMENT REGULATORY AUTHORITY (PPRA) EPADS

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.3 PAKISTAN ENVIRONMENTAL IMPACT ASSESSMENT (EIA) APPROVAL PROCEDURES

Various steps encountered in the submission, review and approval of an IEE or EIA Report under Schedule-I and Schedule-II are shown in Figure 2.1.

3.3.1 Guidelines for Environmental Assessment

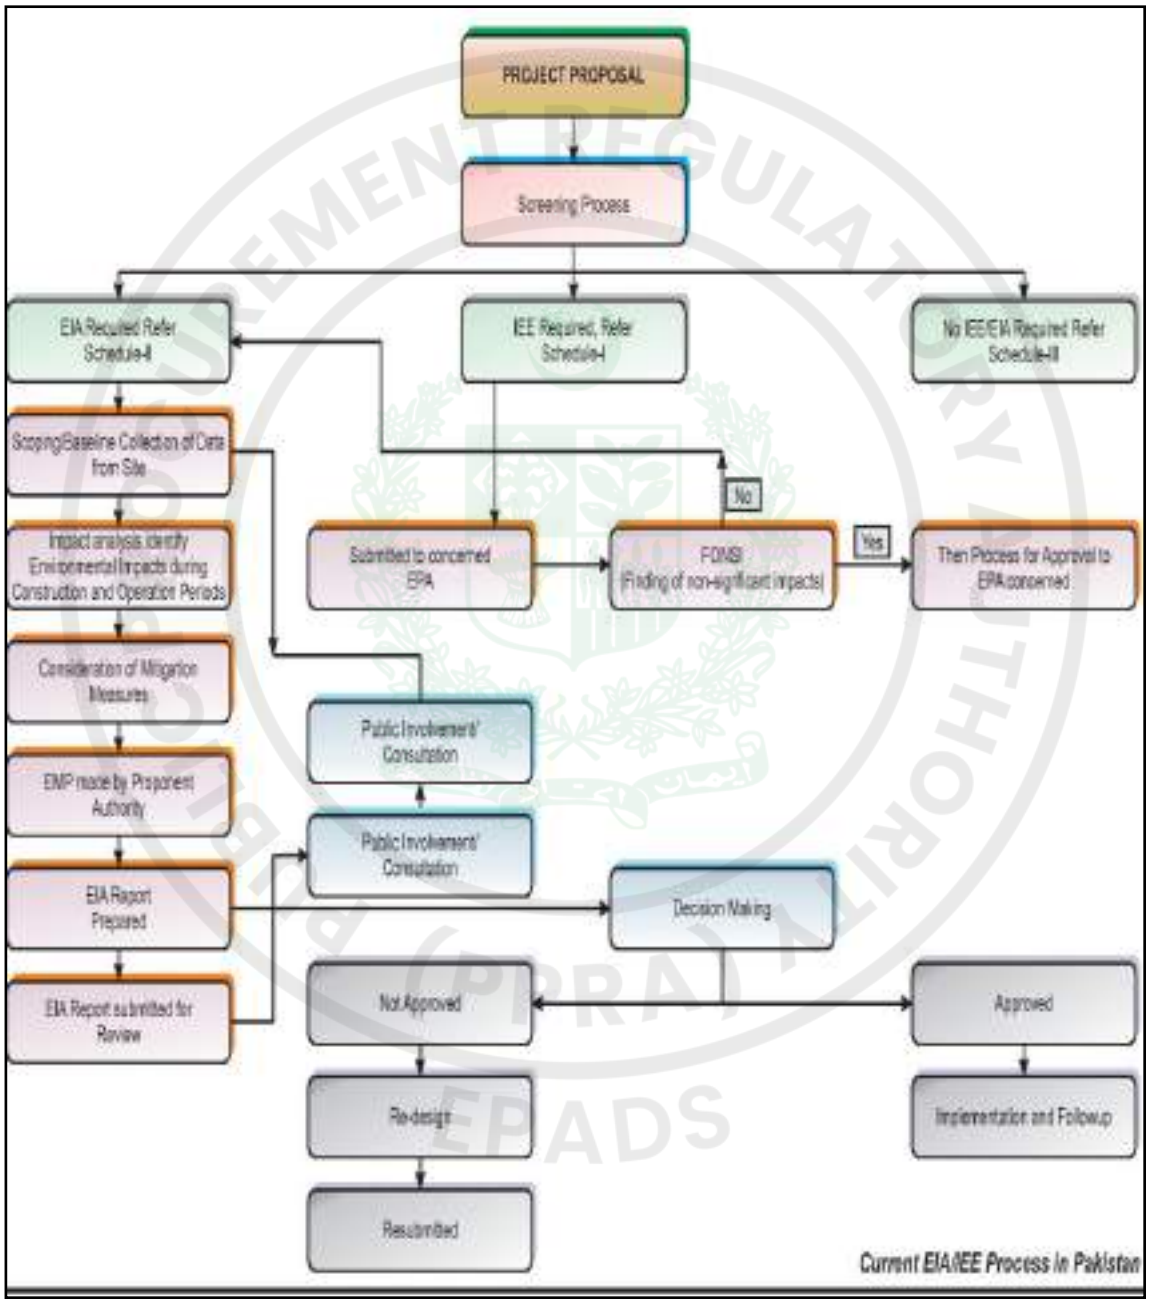

Figure 3-1: Environmental Approval Procedure

Pak-EPA has published a set of environmental guidelines for conducting the environmental assessments and the environmental management of different types for the development Projects.

The guidelines are relevant to the proposed Projects are listed below.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

a) Guidelines for the Preparation and Review of Environmental Reports, Pakistan Environmental Protection Agency, 1997

b) Guidelines for Public Consultation, Pakistan Environmental Protection Agency, May 1997.

c) Sectorial Guidelines: Pakistan Environmental Assessment Procedures, Pakistan Environmental Protection Agency, October 1997.

Required Permits This section describes the procedure for obtaining NOCs for EIA from concerned authorities and for working in sensitive and critical areas, as shown in Figure 3.1

3.4 FEDERAL STATUTORY FRAMEWORKS FOR ENVIRONMENT MANAGEMENT AND ASSESSMENT

This section outlines the important statutes apart from Pakistan Environmental Protection Act, 1997, which are relevant to the Project.

3.4.1 Land Acquisition Act (LAA), 1894

This Act is the primary law for acquisition of land and built-up properties for public interest in Pakistan and also sets out the procedure and rules for acquisition and compensating the owners, as well as for compensating owners for damage caused to their properties, crops and trees by a project but it lacks the mechanism to address the complex issues of resettlement. It comprises 55 sections dealing with area notifications, surveys, acquisition, compensation, appointment awards, disputes resolution, penalties and exemptions. The latest revisions and amendments including Land Acquisition Rules were made in 1983. Presently, the Land Acquisition Act 1894 is applicable throughout Pakistan including Gilgit Baltistan. The valuation of land for compensation is governed by sections 23 and 24 of the Act, which include the following provisions:

- Market value of the land at the time of notification of Section 6
- Damage sustained by a person interested in taking of compensation of standing crops or trees
- Damage sustained by the person at the time of Collector's taking possession of land
- Damage sustained by the person at the time of acquisition of land injuriously affecting his other property, movable or immovable.

For the Attabad Hydropower Project compensation for acquisition of land for project operations and hearing of complaints will be carried out primarily in the light of this Act, supported by other measures (to be decided in the particular circumstances to suit the requirements). However, in case a need arises, this Act will be used for this purpose, supported by other measures as warranted, to fulfill requirements of the World Bank Guidelines. In the project area mostly land ownership belongs to the community, people living in valleys have ownership rights on the local rangelands. The community has unwritten traditional laws for possession, distribution and transfer of assets or the income of the assets to the original inhabitants of these valleys.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.4.2 Project Implementation and Resettlement of the Affected Persons Ordinance 2000

The Government of Pakistan has proclaimed an ordinance entitled "Project Implementation and Resettlement of the Affected Persons Ordinance 2001", later referred to as the “Resettlement Ordinance". This ordinance will be used to safeguard the interests of persons and groups involuntarily displaced from the existing places to new resettlement areas. This ordinance establishes that the resettlement of the involuntarily displaced persons is done as a matter of right and not by way of charity or any such sentiment, also the PAPs will be accepted as special groups, who in the interest of the project have accepted and undergone involuntary displacement. However, as far as Attabad Lake HPP is concerned, there is no displacement involved for the project there will no resettlement.

3.4.3 Antiquities Act 1975

The Antiquities Act of 1975 ensures the protection of the cultural resources of Pakistan. All the archaeological sites, artefacts, historical carvings, historical monuments, temples, shrines, old graveyards etc. come under the cultural property. The Act is designed to protect "antiquities" from destruction, theft, negligence, unlawful excavation, trade and export. The law prohibits new construction in the proximity of a protected antiquity and empowers the Government of Pakistan to prohibit excavation in any area which is of archaeological significance. Under this Act, it is understood that all project proponents are obliged to:

- Ensure that no activity is undertaken in the proximity of a protected areas without permission of the competent authority
- In case any antiquities have been found or reported in any project area it will be the responsibility of the proponent to report to the Department of Archaeology, Government of Pakistan

3.4.4 Pakistan Water and Power Development Authority Act 1958

The Act provides for the unified and coordinated development of the water and power resources of Pakistan. This Act authorizes WAPDA to develop water and power resources in the country through construction and operation of water storages and power houses and erecting electrical transmission lines with powers and obligations of a licensee under the Telegraphy Act of 1910. This act also establishes policy for land acquisition and compensation, as well as the degree of liability of WAPDA for damages sustained by landowners or others.

3.4.5 The Telegraphy Act 1910

This act was promulgated for the installation of telegraph poles and lines. This Act makes provision of installing poles and towers without acquiring any land. However, provision is also made for temporary acquisition of land during the construction period. As such, compensation is made for the loss of crops for a specific period.

3.4.6 Labor Laws

Labor laws in Pakistan are governed by several legislative tools. However, the principal labor rights are provided by the constitution of Pakistan. The following articles enforce key labor rights.

- **Article 11** of the constitution prohibits all forms of slavery, forced labor and child labor
- **Article 17** provides for a fundamental right to exercise the freedom of association and the right to form union
- **Article 18** prescribes the right of its citizen to enter upon any lawful profession or occupation and to conduct any lawful trade or business
- **Article 25** lays down the right to equality
- **Article 37 (e)** makes provisions for securing human conditions of work, ensuring that children and women are not employed in vacations unsuited to their age or sex, and for maternity benefits for women employment.

In addition to constitutional rights, Acts and Ordinances have been enforced for limiting working hours, minimum working age, and conditions of employment.

3.4.7 Penal Code 1860

The Pakistan Penal Code deals with offences where public or private property and/or human lives are affected due to the intentional or accidental misconduct of an individual or body of people. In the context of the environment, the Penal Code empowers local authorities to control noise, toxic emissions and disposal of effluents.

3.4.8 Local Government Ordinance 2001

This Act empowers the Government of Pakistan and provincial governments to enforce laws for land use; conservation of natural vegetation; air, water, and land pollution; disposal of solid waste and wastewater effluents; and public health and safety, including some provisions for environmental protection. Section 93 of this Ordinance pertains to environmental pollution, under which the local councils are authorized to restrict causing pollution to air, water or land. They may also initiate schemes for improving the environment. The Local Councils of the project area have been consulted for their views on the project interventions, and mitigation being proposed for the likely impacts.

3.4.9 Regulations of Mines and Oil Fields and Mineral Development Act, 1948

This Act provides regulatory procedures for the quarrying and mining of construction material on public as well as private lands.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.4.10 Motor Vehicle Ordinance 1965

The Motor Vehicles Ordinance of 1965 of Punjab was extended to the whole of Pakistan in 1978. The ordinance deals with the powers of the Motor Vehicle Licensing Authorities and empowers other related agencies to regulate traffic rules, vehicle speed and weight limits, and vehicle use, to erect traffic signs, and to prescribe special duties of drivers in case of accidents. It also prescribes powers of police officers to check and penalize traffic offenders. At the same time, the ordinance also empowers the regional transport authority to operate as a quasi-judicial body at district level to monitor road transport, licensing requirements, and compensations for deaths or injuries to passengers on public carriers.

3.4.11 Factories Act, 1934

The clauses relevant to the project are those which concern health, safety and welfare of workers, disposal of solid wastes and effluents, and damage to private and public property. The Factories Act also provides regulations for handling and disposal of toxic and hazardous materials. As construction activity is classified as 'industry', these regulations will be applicable to the project construction contractor.

3.4.12 Highways Safety Ordinance 2000

This ordinance includes provisions for licensing and registration of vehicles and construction equipment; maintenance of road vehicles; traffic control offences, penalties and procedures; and the establishment of a police force for motorways and national highways to regulate and control the traffic as well as keep the highways clear of encroachments.

3.4.13 Explosive Act, 1884

Under the Explosives Act, the project contractors are bound by regulations on licensing, handling, transportation, storage and using explosives during quarrying, blasting, and other purposes.

3.4.14 Wild Life Act 1975

The Wild Life Act is an Act to amend and consolidate the law relating to protection, preservation, conservation and management of wildlife in the country.

3.4.15 Private Forest Regulation 1970

Forests in state ownership in the Gilgit-Baltistan have been designated as "protected forests" under the Pakistan Forest Act (1927). The other legal category of forests here is "private forest" which are owned by the local communities. These forests are legally covered under the Gilgit Private Forests Regulations (1970) and the rules framed thereafter.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

3.4.16 The Forest Act, 1927 and later amendments

This Act establishes the right of the Government to designate areas for reserved forest, village forest and protected forest, and may acquire such areas for prohibiting or restricting the public use of the resources or other activities.

3.4.17 Protection of Trees and Brushwood Act, 1949

This Act prohibits cutting or lopping of trees along roads and canals planted by the Forest Department, without permission of the Forest Department.

3.4.18 Gilgit-Baltistan Customary Laws

In NA customary laws are also practiced besides national laws. This system provides for at least one authority, chosen by the community either by nomination or election, with responsibility for managing natural resources and enforcing customary laws. This customary normative framework includes provisions for: community and individual ownership; resource use fees; and fines as penalties for violations of these laws. Most of the occupants, who claim to be the owner, do not have any written tenancy agreement. For such cases in the non-settled area, confirmation by the village jirgas on land possession is accepted at community, court and local administration levels. Adoption of current 'Gilgit-Baltistan Neuter Rule' (1980) envisages that the occupant of land will be treated as its owner. All other land beyond the settlements, mostly barren, will belong to the Gilgit-Baltistan Administration. This position was also reaffirmed by the Courts of NA.

3.4.19 Gilgit-Baltistan Forest Rules 1983

The Gilgit-Baltistan Forest Rules protected forests which are either the property of the government or have property rights to the whole or part of the forest produce. However local people may have some concessions and user rights. They may be able to use these forests for grazing and collection of fuel wood and other non-timber products.

3.4.20 Gilgit-Baltistan Strategy for Sustainable Development 2003

The Gilgit-Baltistan Strategy for Sustainable Development presents a vision and a strategic framework for economic, social, cultural, and ecological well-being of the people of the Gilgit-Baltistan. It provides a road map to improve governance, integrated gender, environment and sustainability, prioritized development needs, and creation of an enabling environment by improving policies and legislation.

3.4.21 Draft National Forest Policy 2001

A draft of the National Forest Policy was prepared in 2001 which is also applicable to the Gilgit-Baltistan. It emphasizes the sustainable use of natural resources with community participation and recommends that timber harvesting be used for poverty alleviation. It also aims to rehabilitate the environment.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4 BASELINE CONDITIONS

This section provides baseline data (physical, biological and socio-economic parameters) related to the project area. Information provided is both quantitative and qualitative and is based on secondary and primary data collected, site field visits and desk studies. A baseline consists of the existing environmental and socio-economic and cultural status of the project area. The baseline information and indigenous knowledge is required for scoping potential environmental issues associated with the implementation of the project. On the basis of baseline information, the project interventions are assessed and mitigation measures are proposed. The baseline information also helps to indicate the specific issues to be monitored during project execution as well as during operational phase.

4.1 PHYSICAL ENVIRONMENT

4.1.1 Physiography

The project area is located in Gilgit-Baltistan (N.A) of Pakistan in district Hunza. Hunza is a mountainous region forming the western part of the Karakoram and Eastern Pamir mountain range. The area generally consists of rugged and precipitous terrain classified as alpine scrub zone and is characterized by heavy snowfall at higher altitudes in winter.

The site of the project is located on Hunza River at Attabad Lake about 15km upstream from Ganish Bridge of Hunza. Its distance is about 20 km from Hunza, 115 km from Gilgit. The powerhouse location is on the left bank of river and easily accessible from Karakoram Highway. The intake weir/dam site is selected at current exit point of Attabad Lake which is was formed in the year 2010 due to a huge slide from right bank mountain, however, some portion of left bank mountain was also damaged.

People of all the nine villages within the project area are mostly dependent on agriculture and livestock. The dam and reservoir fall into the jurisdiction of Hunza district.

The Hunza River in the study area is the principal river of Hunza and Nagar Districts in Gilgit-Baltistan. It is formed by the confluence of the Chapursan and Khunjerab Nullahs (gorges) which are fed by glaciers. It is joined by the Gilgit River and the Naltar River, before it flows into the Indus River near Juglot.

4.1.2 Demography

Hunza valley is mainly divided in three parts with different tribal structure. The people living in Gojal had migrated to this part of Hunza from Wakhan, Pamir, and Badakhshan before the end of 18th century. They are mostly Wakhis (from Wakhan, a strip of land between Central Asia and Pakistan), an ethic group staying in the mountainous areas of the Karakoram and the Pamirs in the border land of Pakistan, China and Afghanistan. The language and culture distinguish them from Brush and Shina speaking people, who live in central and lower Hunza.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.1.3 Climate

The climatic parameters that influence the climate of an area include temperature, precipitation, humidity and evaporation. Situated in the western most arm of Karakoram range, Hunza is found within semi-arid and rugged mountain landscape (mountain desert). The climate varies widely from monsoon-influenced moist temperate to arid and semi-arid cold deserts in the north. In general, two seasons prevail in the project area: winter (October to March) and summer (April to September). The Northern Areas have the high mountain ranges of the Himalayas, Karakoram and Hindukush ranges with elevations rising to over 8,000 m, which result in altitude being the dominant influence on the climate of the region. These ranges act as climate barriers between the Indus basin and Central Asia to the North, and the main part of the sub-continent to the South.

4.1.4 Precipitation

Rarefied air, intense solar radiation, strong winds, and vast ranges of temperature are the characteristic climate of the area. Below 3000 m, precipitation is less than 200 mm per annum while there is a sharp precipitation gradient along the altitude, and over 2,000 mm annual snow fall above 6000 masl. Precipitation in the form of rainfall is not sufficient to contribute significantly in meeting either crop water requirements or stream flows. The snow- and ice-melt are the major sources of precipitation contributing to the available water resources in the GB. Irrigation is based on water resources from glaciers, rivers and streams. Average Monthly and annual rainfall recorded at WAPDA High Altitude Weather Station has been given in Table-4.1.

The Hunza River catchment upstream of the dam site is highly mountainous generally with low precipitation. The low precipitation particularly during the hot (monsoon) season coupled with less catchment area likely to experience rainfall are the factors responsible for low runoff or poor contribution to flood producing mechanism source.

4.1.5 Temperature

The Northern Areas of Pakistan are dominated by one of the most mountainous landscapes on earth, with an arm of the Hindu Kush to the west, the lesser Himalaya to the south, the Karakoram to the east and the Pamir to the north. More than half of the Northern Areas is located above 4,500 meters. Temperatures in the valley bottoms can vary from extremes of 35°C in summer to less than –15°C in winter.

The summer season in Hunza Valley is cool while winter is chilly. Wide spread snow fall occurs in winter. During winter the northern winds blow constantly bringing the temperature down considerably. At Hunza, the mean temperature is 30.20 °C in July, the hottest month and the coldest month is January with an average temperature of -3.5 °C. The mean minimum temperatures are 21.9 °C in July and -7.3 °C in January respectively. Hunza like other areas in extreme north-west of Pakistan receives only 136 mm precipitation of which 40% occurs in Winter and Spring.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The Gilgit Meteorological Station is the nearest station to Hunza valley that has a sound historical record covering more than five decades.

Table 4-1: Average Max & Min Monthly Temperature and Mean Precipitation at Gilgit

Month	Mean Min Temp (°C)	Mean Max Temp (°C)	Mean Prec. (mm)
Jan	2.4	9.4	4
Feb	0.7	12.6	6.8
Mar	5.7	18.2	0.14
Apr	9.5	24.1	23.8
May	12.1	28.6	24.5

Nov	0.9	18.2	2.4
Dec	-1.9	11.5	5.1
Annual	**7.9**	**23.8**	**133.1**

4.1.6 Wind Speed and Direction

Wind speed is a highly variable parameter especially at high altitudes complex terrains and depends on the local conditions of the specific catchment. Computation of realistic wind speed is therefore very difficult due to its temporal and spatially varying nature in the mountainous regions.

The speed and direction data of Hunza Valley is not being recorded, however, data of some adjacent stations to project area are given in Table 4.2.

Table 4-2: Wind Speed and Direction

Station	Calm	N	NE	E	SE	S	SW	W	NW	Mean Wind Speed	Maximum Observed Speed
Percent of Total Time (%)										Knots	
Astore	50	17	1	0	0	29	1	0	1	3.0	29.0
Gilgit	74	0	1	4	7	1	1	9	2	2.0	28.0
Skardu	80	0	2	2	0	9	5	3	0	2.9	69.0

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Wind speeds tend to be higher between April and September and lowest from November to January. However, these averages conceal the fact that often the wind is accumulated over short bursts of gusty convectional wind especially during the late spring and summer when heating effects cause strong but short lived convectional winds.

4.1.7 Geology

Tectonically, project area lies in the Karakoram Block towards the north of the Karakoram Thrust (MKT) and Main Mantle Thrust (MMT) which are considered to be the manifestation of the tectonic collision between Indian Plate (Continent) with the Kohistan Island Arc and then with the Eurasian plate (Continent). This continent to continent collision has given rise to three most famous orogenies in the world. The Himalaya, Karakorum and Hindokush are considered to be the highest mountainous ranges in the world.

The Glacio fluvial deposits forming the site of Attabad village consist of boulders, cobbles and gravels with some silt and sand as cementing material. The rocks exposed at the crown and toe; are highly fractured, sheared, jointed and weathered. A fault on the eastern side of the village is passing through Hunza River trending almost North-South. The re- sediment till deposits flank both sides of Hunza River in the power house area. These tills comprise extremely fine grained (powder) soapy-touch clays.

4.1.8 Seismology

The project area lies in the region of Northern Pakistan which has high frequency of earthquakes especially in the Himalayan orogenic belt. This belt represents the contact between Indo-Pak and Eurasian plates, which has always been the source of moderate to large earthquakes including Kangra (1905), Bihar-Nepal (1934), Assam (1897) and 2005 Kashmir earthquakes with significance consequences. The presence of some of the active faults like Main Karakorum Thrust (MKT), Main Mantle Thrust (MMT), Raikot Fault, Riwat Fault, Panjal Khairabad Fault, Jhelum Fault and Main Boundary Thrust (MBT) etc make the northern Pakistan region tectonically very active.

In October 2005, an earthquake of very high intensity (7.8) hit the area near Muzaffarabad and disturbed the ground to a significant extent in that area. The geological, tectonic and geodynamic conditions of the project area have been assessed and detailed mapping of the ground surface has been done to define the geology and tectonic features of the area.

4.1.9 Landslides, Erosion and Sedimentation

The glaciers of the Gilgit Baltistan and KPK have very high “activity indices”, an index for the total amount of water passing through the glacier system per annum. As a result, they have high flow rates in terms of the glacier melt, ranging between 100 and 1,000 meters/year. As a result of these high rates of flow, these glaciers aggressively erode their beds and transport the eroded materials to the headwaters of rivers, which causes the transport of sediments into the major rivers of the region. The exact proportion of sediment due to glacial erosion is still not measured;

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

however, it could be stated that these account for the huge load of the sediments passing through the upper Indus system especially Hunza River, Shyok River and Shiger River.

Landslides are very common features in the project area because of the high steep terrain. Erosion and sediment input to the river is a function of landslides and riparian erosion processes. There are frequent talus accumulations along the side slopes of the river. These are typically in a state of stable equilibrium at their current slope angle and environment but become unstable when the equilibrium is disturbed. Excess water and earthquakes often trigger landslides.

4.1.10 Land Use

There are nine villages located on alluvial fans and terraces on both sides of the Hunza River and its tributaries where water is available for human consumption and agriculture. The mountains on both sides of the reservoir have steep slopes and many streams and nallahs join the river in this length. The nallahs span out near the confluence of the river, forming some cultivable land masses as can be witnessed near Passu village. The alluvial fans contain clay silt layer with an undulated topography over hard bedrock. The available flat land is used for residential purposes as well as for agriculture, orchards and grazing for cattle, goats and sheep etc. The total geographic area of the Hunza valley is about 8,920 Km^2. Summary of land use in the Gilgit Baltistan is shown in Table 4.3.

Table 4-3: Summary of Land Use in Gilgit-Baltistan

S.No.	Type of land	Area Million (Hectares)	Percentage (%)
1	Mountain/Lakes/Rivers/Glaciers	4.810	66.3
2	Protective Forests	0.065	0.89
3	Private Forests	0.219	1.78
4	Social/agri Forests	0.368	5.07
5	Range lands	1.626	22.4
6	Cultivable Area	0.078	1.1
7	Cultivable Waste	0.090	1.2
Total		7.250	100%

Source: Statistical Unit GBP & DD 2013

A land use survey was carried out in the villages falling in the reservoir, dam site and power house areas.

The area is rugged and mountainous. The cultivated lands are concentrated in alluvial fans near habitation. Rest of the area is either under Forests/Pastures and the remaining is barren land belonging to the Government/Communities.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.1.11 Mining

Mining is one of the common professions in small parts of the project area. Local people have developed mining at their own level with their own resources. Small horizontal mines have been excavated by local explorers. The area near the lake is rich in mineral resources however their exploitation as commercial use is still not being done. There are archeological sites were observed and reported during field investigations. People use to explorers the Mines by their own resources without any support of Government.

4.1.12 Soil Pollution and Contamination

There is no industry, commercial area, poultry farm, vehicular washing lines or any other source of contaminants in the project area which could cause soil pollution or contamination through liquid and solid waste generation. The agriculture is practiced on a limited area and limited farm yard manure is used for crop production. Use of chemical fertilizers, pesticides and insecticides is also limited.

4.1.13 Agriculture

The area under agriculture is approximately 112,688 ha or 1.6% of the total area Gilgit Baltistan. Because the climate is arid, agriculture depends on irrigation through water channels locally known as (kuhls)-that bring water through gravity flow from streams fed by glacier or snow melt. It is estimated that another 90,000 ha can be brought under farming by irrigation. Almost 80 per cent of the GB's population is engaged in subsistence agriculture. While GB exports fruits and potato to other parts of the country, it has to import of cereals, poultry and other food products to meet the needs of growing population Agricultural in GB has can be divided into two broad cropping zones depending on the elevation. At elevations between 1200 and 2000 m.s.a.l both summer and winter crops are grown, however, in areas situated in between 2000 m.s.a.l and 3000 m.s.a.l a single summer crop can be grown.

In Hunza District, a mixture of different activities is followed in the farming system. There may be some variation in the farm size or in the status of minor crops in the overall cropping practices but the general combination of crops, livestock and other farm related activities are more or less the same. Wheat, barley and vegetables are the main Rabi crops. Whereas Maize, potato, millet and pulses are Kharif crops. Shaftall and Lucerne or Alfalfa is grown as a perennial crop which is the most popular fodder for livestock throughout the year. Majority of the trees are grown on the field boundaries.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 4-4: District Wise Agriculture Land of GB

District	Agriculture Land (ha)	Percentage Cover
Astore	8133.43	1.51%
Diamer	9058.52	1.26%
Ghanche	11966.75	1.35%
Ghizer	16431.94	1.34%
Gilgit	10167.94	2.44%
Hunza-Nagar	12013.87	0.8%
Skardu	30589.88	1.56%
Total	**98362.33**	**10.26%**

Most of the agricultural activities in Hunza are carried out on the terraces prepared in the vicinity of settlements.

Table 4-5: Cropping Pattern in Hunza valley

Date of Land Preparation	Crops/Vegetables	Fruits	Fodder
May	Wheat, Potato, Peas	Apples, Apricot	Alfalfa
March-April	Wheat, Barley, Potato, Peas, Turnip, Buckwheat	Apples, Apricot Walnut, Mulbery	Alfalfa
March-April	Wheat, Maize Barley, Potato, Peas, Turnip, Buckwheat.	Apples, Apricot, Walnut, Mulbery	Alfalfa
March-April	Wheat, Barley, Potato, Peas, Turnip, Buckwheat	Apples, Apricot, Walnut, Mulbery	Alfalfa
March-April	Wheat, Barley, Maize, Potato, Peas, Turnip, Buckwheat	Apples, Apricot, Walnut, Mulbery Almonds, Grapes	Alfalfa
March-April	Wheat, Barley, Potato, Peas, Turnip, Buckwheat	Apples, Apricot, Walnut, Mulbery	Alfalfa

Average land per household for wheat is 10 kanals. Average wheat production in the area is 1.8 monds per kanal. Average barley production is 1.5 monds per kanal, which is grown for cereals and barley has short duration. As a yield of wheat straw is 3.3 monds per kanal and barley 2.2 monds per kanal. After harvesting the first crop, both maize is gown for fodder, or turnip and cereals are enough for 4 months and straw sufficient for 5 months.

Grass and fodder are stored during autumn for long winter. On average every household has 9 kanals of land allocated for grass. About 75% households rely on traditional grass, where as 17%

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

for maize or grass. Average production of fodder per kanal has been 4.5 monds. Each household collects and stores at least 30 monds of grass per year, to feed animals in winter.

Table 4-6: Cropped Area and Production

Crop	Wheat	Maize	Barley	Potato	Vegetable	Fruits	Fodder	Total
Area (hectare)	886	970	223	3267	128	3578	1572	10633
Production (Ton)	1570	2713	361	48285	1455	30483	7449	92316

Very little chemical fertilizer is applied to wheat. However, chemical fertilizer is normally applied to potato crop. Application of fertilizer is conditional with the availability of money at the time of planting the crops. The total crop area of Hunza Nagar is 9344 Hectare, 0.73 Hectare per family and about 0.081 per capita.

Irrigation intervals reported for maize were 10 to 15 days depending on the rise in temperature and grain filling periods. Harvesting is done by a serrated sickle and threshing is done either by hand or trampling of grain by oxen.

The agriculture undertaken in the project area is mainly subsistence farming, as land does not produce enough to feed the family. The estimated average yield of crops per household is estimated as 10 mounds (1 mound = 40 kg) of wheat, 15 mounds of maize and 5 monds of Barley per year. The extended family system ensures sharing of the field produce and none is marketed. It was also reported that cereals are only sufficient for four months in most cases and for eight months in few other cases. Agricultural Department and AKRSP are introducing new varieties of cereals but it has not yet been adopted fully.

The cultivated lands and orchards are irrigated from the nallas. These nallas are the only source of water to irrigate all the surrounding villages. Therefore, the village faces scarcity of irrigation water during cropping season.

4.1.14 Fruits

Gilgit Baltistan is producing many fruits like apple, cheery, walnut, and apricot. But apricot is more famous for its test and quality. Pakistan produces approximately 300,000 tons of fresh apricot, making it the world's fourth largest producer. Gilgit Baltistan (GB) and Baluchistan are the two main apricot growing regions in Pakistan, with GB alone producing 114,286 tons in 2007. Planting density is only 230 trees/ha, which is much less than the recommended 750 trees/ha, due to apricots being planted around field edges, rather than orchards. Average yields of fresh fruit are 38kg/tree which are good considering the limited use of inputs, although yields of 50kg/tree can be achieved through improved management.

Special importance is given to the cultivation of fruits. Fruits are grown for household consumption as well as for sale in the dry form. Various fruits are grown in Hunza valley. At higher altitudes

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

there are no fruit trees, but in lower portion of Hunza valley several types of fruit are grown. Major fruits are apricot, apple, mulberry, grapes, almond and walnut. It has been calculated on average that every household has 22 trees out of which 15 are fruit bearing trees. The average production of fruit by each tree is 50 kg. Average fruit available to each household is 20 monds. Fresh fruit is consumed at home and there is no marketing of fruit.

Table 4.7 shows Area and Production of Fruit in Sub division Hunza.

Table 4-7: Area and Production of Fruit in Sub division Hunza

Fruits	Fruit Bearing Trees	Non Fruit Bearing Trees	Total Trees	Area (ha)	Production (Ton)
Apricot	140078	59755	199833	869	9629
Apple	68660	23515	92175	401	2321

4.1.15 Livestock

The people of entire Hunza River the livestock reared by almost all households. Usually with the snow melt, goat, sheep and cows giving no milk are taken to the alpine pastures for grazing. They stay there during the summer season and are brought back with the onset of snow on the top of the hills. When the animals are brought to the village they are grazed in the agricultural fields of maize crop residues. All the milking animals are kept in the houses and stall fed. In general women take care of all animals in the houses and graze cows around the village on pastoral lands. These are situated between agricultural and forest land and are covered with grasses intermixed with oak stands. Only men take small animals i.e., goats and sheep to the alpine pastures. Normally a herders belonging to the same village collects other farmers animals and take them to alpine pastures for grazing during summer. These herders keep all the milk produced at pastures in lieu of herding charges. They convert this milk into ghee and other dairy products for their own use and marketing. The number of domestic animals the villagers owned has decreased over the past few decades due to decrease in grasses near the villages.

Livestock contributes a great deal to the local economy. However, physical condition and general health of the animals is not satisfactory, especially in winter due to the shortage of fodder. Bullocks are the main source of farm power, but they are hardly capable of drawing plough due to poor health. Cows, sheep and goats are also lean and thin. Animal diseases cause considerable losses to the livestock. Productivity of cattle is generally low because of severe winter and lack of proper feed. Meat, milk, butter and eggs are the main animal /poultry products but most of these are consumed at the household level. At some places milk, meat, animal hides, wool and poultry are sold.

The livestock is also a social and financial capital of the family. Every family keeps some extra heads to be sold or slaughtered on occasions of marriage or death in the family. A few heads are kept to be given as dowry to daughters on their wedding. The livestock numbers far exceed the carrying capacity of natural pastures and available forage resources.

4.1.16 Hydrology

The Karakoram and Himalayan mountains form the main source of snow and ice melt runoff to the Indus River System. The precipitation enhancing and shadowing effects of the main mountain ranges provide dramatic contrasts that greatly complicate the hydrological picture. The main tributaries of Hunza River are; Chapursan, Kilik, Bola Das joining the Hunza river from the west and Khunjerab along with Ghujerab, Simshal and Hispar Rivers joining river from the east of the valley. The river flows of Hunza are usually maximum in the month of July when snow and glacier melt is at its peak while these are minimum in the month of March when snow and ice melting is insignificant.

There is only one hydrological gauging station on Hunza River at Danyore Bridge being operated by SWHP-WAPDA. This station is located at about 107 kilometers downstream of Attabad Landslide Dam Location. The catchment area of Hunza River upto Danyore gauging station is 13,157 km^2, whereas it is 14,083 km^2 upto its confluence with Gilgit River. Hunza River catchment area is 8,901 km^2 upto Attabad Landslide Dam Location. Therefore, river flows are transposed and estimated from documented discharge data from hydrological station at Danyore. Daily discharge data from 1966 to 2015 is available and processed for the calculations. Data for year 2016 was incomplete, missing the values of high flow months, and there was no record of hydrological data for the period 2017 to 2018 at SWHP therefore, it was not used in the calculations. Mean annual flows are calculated and drawn in the figure below for the period 1966-2015. Average value for mean annual flow has been calculated as 208.36 m^3/s.

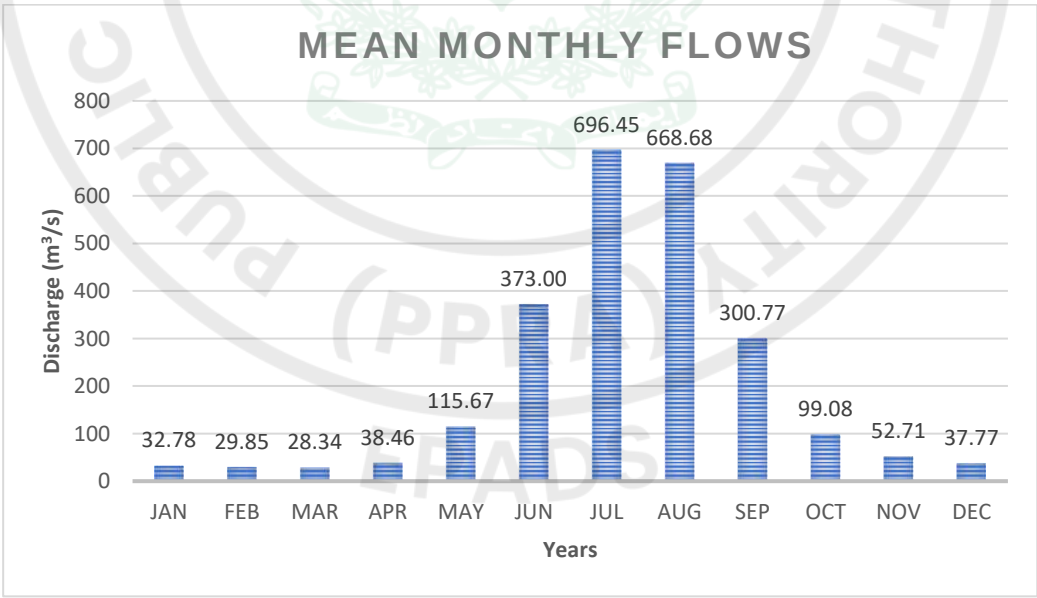

Figure 4-1: Mean Monthly Flows

Flows are generally maximum in July and August almost reaching 700 m^3/s. Whereas, flows are low from December to April each year when snow falls in the catchment. The record shows that design discharge of 60 m^3/s is available for about half year (almost 6 months). Graph shows that flows are exceeding the design discharge from June to mid-December which shows the potential of hydropower generation.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.1.17 Flooding

The maximum peak discharges of mean daily for every year recorded. The instantaneous peaks will definitely be higher than the measured daily flows and can be enhanced while execution accordingly. Instantaneous peak flows for the period 1966 to 2015 has been calculated and plotted as well.

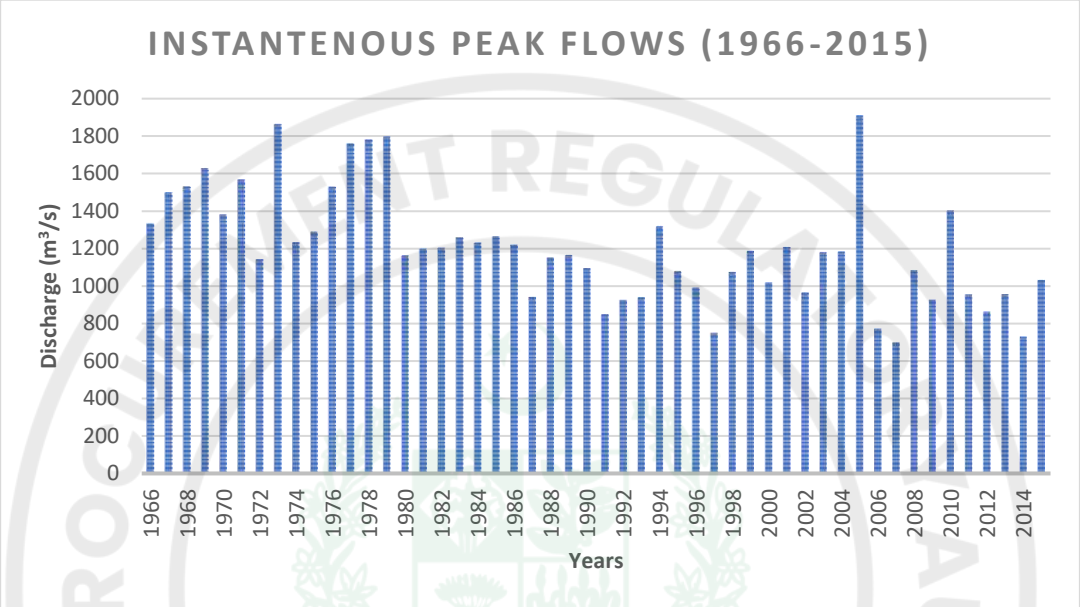

Figure 4-2: Instantaneous Peak Flows at Attabad Lake HPP Site

4.1.18 Surface Water

In the project area, the Hunza river carries water of various streams (nallahs)of snowmelt, and rainwater fall. The people use the water of these nallahs for drinking, household and agriculture purposes. Generally, there is no shortage of clean potable water in the project area as it is very difficult to fetch the water of river and nallahs due to the very steep slopes. People mostly use water from nallahs for drinking, washing and other domestic purposes. During the socio-cultural survey of the project area, many of the respondents from the villages falling in the project area reported stomach, skin, bones, diseases. Initially, rainwater as well as snowmelt water do not contain significant impurities. As these waters flow over land they pick up sediments, salts, toxic elements, pulverized organic matter and bacteria from the surface. Water samples were taken in November 2020 covering the complete affected area within the project area. The laboratory results of these samples summarized in Table 4.12 & 4.13 and detail at **Appendix-C** reveal that all the parameters are within the permissible limits when compared with drinking water quality standards of WHO, except the presence of Escherichia coli pathogenic bacteria which causes gastroenteritis in human beings.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 4-12: Chemical Parameters Results of the Samples (Surface Water)

National Standards for Drinking Water Quality of Pakistan (mg/l)									
Nitrate	**Nitrite**	**Cu**	**Al**	**Fe**	**Mn**	**Cr6**	**Zn**	**Ni**	**B**
≤50	≤3	2.0	≤0.2	-----	≤0.5	≤0.05	5.0	≤0.02	0.3

Sr. No	**Location from Sample Collected**	**Test Results (mg/l)**									
		Nitrate	**Nitrite**	**Cu**	**Al**	**Fe**	**Mn**	**Cr6**	**Zn**	**Ni**	**B**
1	Hunza River Side before Confluence of Shamshal Nullah	ND	ND	0.4	ND	ND	ND	0.03	ND	0.01	ND
2	Shamshal Nullah before entering Hunza River	ND	ND	0.07	ND	0.04	ND	0.02	ND	0.02	ND
3	Hunza River Side Near Power House	ND	ND	0.2	ND	0.3	ND	ND	ND	0.01	ND
4	Attabad Lake Boating Area	1.3	ND	ND	ND	ND	ND	0.03	ND	0.02	ND
5	Gulmit Tap Water	ND	ND	0.02	ND	ND	ND	ND	ND	0.01	ND
6	Gulmit Glacier Near Hunza River	ND	ND	ND	ND	ND	ND	0.14	ND	0.2	ND
Conclusion:	The concentrations of nitrate, copper, iron. Chromium 6 and nickel are within National Standards for Drinking Water Quality of Pakistan for first four areas.

Table 4-13: Bacteriological and Physical Parameters Results of the Samples (Surface Water)

Bacteriological Parameter	National Standards for Drinking Water Quality of Pakistan (Physical Parameters)						
E.coli	**pH**	**Turbidity**	**Total Dissolved Solids**	**Electrical Conductivity**	**Color**	**Odor**	**Taste**
0/100 ml	6.5-8.5	<5 NTU	<1000 ppm	2000 µs	Un Objectionable	Un Objectionable	Un Objectionable

Sr. No	Location from Sample Collected	Test Results								
		Bacteriological	Physical Parameters							
		E.coli	pH	Turbidity	Total Dissolved	Electrical Conductivity	Temp.	Color	Odor	Taste
1	Hunza River Side before Confluence of Shamshal	0 col/100ml	8.4	<5 NTU	67.8 ppm	130.4 µs	7ºC	Clear	Odorless	Tasteless
2	Shamshal Nullah by entering Hunza	0 col/100ml	8.4	15 NTU	98.1 ppm	186.8µs	7ºC	Clear	Odorless	Tasteless
3	Hunza River Side Near Power House	0 col/100ml	8.0	<5 NTU	62.7 ppm	125.4µs	7ºC	Clear	Odorless	Tasteless
4	Attabad Lake Boating Area	0 col/100ml	8.5	<5 NTU	65.4 ppm	129.7µs	7ºC	Clear	Odorless	Tasteless
5	Gulmit Tap Water	0 col/100ml	7.4	<5 NTU	23.5 ppm	47.2µs	7ºC	Clear	Odorless	Tasteless
6	Gulmit Glacier Near Hunza River	0 col/100ml	8.0	<5 NTU	29.7 ppm	59.4µs	7ºC	Clear	Odorless	Tasteless
Conclusion:		Results show that the turbidity in Shamshal Nullah by entering Hunza water sample exceed the National Standards for Drinking Water Quality of Pakistan.								

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.1.19 Tributaries

Nine villages are located in the project area. All the villages are situated near to streams (nallah) fall in main tributaries of Hunza River. Main tributaries of Hunza River are:

- **Khunjerab River** begins in the snow clad mountains and glaciers in the north and south of Khunjerab pass. The river flows to the west then turns southward. It ends when it flows into the Hunza River.
- **Chapursan River** begins in the area of the Chilanji pass and Kampiri Diwar peak. It flows to the east and joins Khunjerab River near Khuda Abad.
- **Misgar River** begins from the mountains of Mintaka and the Kilik pass on the northern boundary of Hunza. It flows to the south east and ends when it falls into the Khunjerab River.
- **Gujerab River** starts from small glaciers and snow-topped mountains of the Gujerab range, and flows to the west and later joins Khunjerab River.
- **Shimshal River** begins in the Shimshal pass from Virjirab and other glaciers. This is in the north eastern region of the Gilgit Region. It flows to the west and after reaching Passu it joins the Khunjerab River.
- **Hispar River** forms from the melt water of the Hispar Glacier - a forty-nine-kilometer-long glacier in the Karakoram Mountains. The Hispar Glacier and river both flow northwest, passing through Hispar, Hopar and Nagar villages until the confluence with the Hunza River.

4.1.20 Groundwater

The project area consists of rocky mountainous terrain. The water originated from rainfall and snowmelt flows through streams and enters into river. Only a small quantity of water has the chance to percolate and form a groundwater reservoir.

4.1.21 Water Availability & Quality

Glacier and snowmelt are the main source of water for domestic use in the valley, while springs are the principal source of drinking water in Gojal tehsil. The melted water gradually enters the streams, which subsequently feed man-made channels - Kuhls - that bring water into the populated areas for agriculture, livestock and domestic purposes.

Piped water supply that covers only 40% of the total population of the Gilgit-Baltistan does not provide safe/ clean drinking water to urban and rural settlements in the region.

In upper Hunza region, drinking water is obtained from glacier melt and piped water only in summer season, because the glacier water freezes in winter for three months. The villagers meet their need of water from the Hunza River.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.1.22 Air Quality and Noise

The air quality of the project area and its vicinity is very fresh and clear under normal condition. There is no major source of air pollution as there are no major vehicular movement or industrial setup in its vicinity.

The vegetation cover in the area is thick and the level of ambient (suspended) dust increases during windy conditions. Being far from the roadside they are not faced with impact of air and noise pollution resulting from transport vehicles. Air and noise pollution has not yet emerged as an environmental issue owing to operation of a small number of vehicles increasing by a fair degree during the tourist season. Based on a number of observations on ambient air quality in rural areas the following range of concentration of gaseous pollutants is estimated on the roadside at Gulmit:

Table 4-14: Range of Gaseous Pollutant Concentration & Noise Emission Level

Range of Variation	CO ppm	SO_2 ppb	NO_x ppb	SPM $\mu g/m^3$	Noise dB(A)
Minimum	0.65	05	05	45	40
Maximum	0.9	10	12	90	70
Average	0.7	07	07	70	55

The noise level near the river is fairly high and range between 50 to 65 dB without traffic, mainly due to the flowing water colliding against rocks and boulders. There is normal traffic on the Karakoram Highway which runs through the Hunza valley. So traffic noise has negligible contribution to the noise level in the project area.

4.1.23 Greenhouse gases

Greenhouse gases are those gases (CO_2, CH_4, O_2, CFCs and NO) which contribute to global warming. The main sources of these gases are industries and vehicles using fossil fuel as fuel. At present there is no industry in the project area that emits greenhouse gas (GHG) and vehicles intensity is also very low. The main sources of carbon and nitrogen oxide emissions are the automobiles being operated in the project area.

4.1.24 Waste

The villages within the project area do not have any drainage, sewerage or treatment system for sewerage collection and disposal. More than50 per cent of the houses have improvised pour flush pit latrines. The remaining 50 per cent of the house hold use locally made toilets, dry pits or defecate in the fields. Wastewater (sludge) from kitchen, bathing and washing is discharged

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

into small drains/water courses leading to the nalaor directly to small fields outside the houses. Modern health facilities are available at Hunza and patients are brought to Hunza for treatment.

There are no special disposal practices or collection in the area. People use their solid waste in the vegetable field as fertilizer. Animal waste especially cow dung is used for farm manure or used for burning after drying (though rarely).

4.2 BIOLOGICAL ENVIRONMENT

Habitat loss is considered as the leading cause of loss of world's biodiversity. Most species need undisturbed habitat to find food, water, shelter, and mates. But people are altering habitats all over the world. In such areas, the activities causing habitat loss include commercial logging (not based on technical and sustainable basis), land development, over-grazing, fuel wood collection, construction of roads, and building new settlements. All these actions change landscapes, natural water flows, and the species composition in the area. Moreover, changes in climate and land use patterns also reducing the amount of snowfall and rain upon which the habitat depends.

The high altitudes, rugged mountains and sweeping glaciers make much of the region uninhabitable. Only two per cent of the Northern Areas estimated to be suitable for agriculture through irrigation by diverting stream water. However, so far only one percent of the total area is being cropped. Approximately nine per cent of the Areas is covered by natural forests and open scrub, 22 per cent area constitutes alpine pasture, and remaining 68% is mostly bare rock, under permanent snow and glaciers.

4.2.1 Flora

A study was carried out on the Biodiversity of Khunjerab National Park (KNP) during May and June, 2006 to establish baseline information about existing plant wealth and wildlife including flora, reptiles, birds and mammals in order to make some vantage points for future monitoring of key wildlife species. Using different direct and indirect investigation techniques, 14 different valleys and Nullahs of KNP were surveyed and observations on various habitats were recorded.

Four types of vegetation zones were identified including Dry Alpine Scrub, Moist Alpine Pastures, Dry Alpine Plateau Pastures and Sub Alpine Scrub and Birch Forests. So far, 62 plant species belonging to 45 genera and 25 families were identified. Of them, 4 grasses and one species of Liliaceae were determined.

The wide variety of climatic conditions in the region, coupled with the extreme variations in altitude and aspect, has created a wide array of vegetation and ecological zones. Five distinct zones can be identified.

4.2.1.1 Dry Alpine Zones and Permanent Snowfields

This ecological zone is characterized by vast glaciers, boulder fields and sheer cliffs. This zone predominates at high altitudes, around the major peaks of the Karakoram Mountains. It covers most of upper Hunza and the northern parts of Baltistan.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.2.1.2 Alpine Meadows and Alpine Scrub

This zone covers the areas between the high valleys and the permanent snowfields, between 3,500 and 3,800 meters. It is characterized by lush, green and well-watered alpine meadows, located on valley bottoms or high plateau surrounding the main watercourses. Alpine meadows occur in almost all the higher regions of Gilgit, Baltistan, Ghizar and Diamir, particularly where mountains extend above the tree line. The meadows support a wide variety of wildflowers, grasses, sedges and other plants.

4.2.1.3 Sub-Alpine Scrub

The sub-alpine scrub zone occurs throughout the higher mountains of the Himalaya, Hindu Kush and Karakoram, and is found in Gilgit, Skardu, Ghizar and Astore. However, it is often confined to small ravines on the upper slopes. The vegetation consists of small deciduous species such as Betula utilis, and evergreens such as Juniperus communis and Rhododendron hypenanthemum.

4.2.1.4 Dry Temperate Coniferous Forest

These forests are usually found on the inner or northerly slopes of the Himalaya, between 1,500 and 3,400 meters. They occur in parts of Gilgit, Diamir and Baltistan Districts, and are characterized by single species stands of conifers. Typical tree species include Picea smithiana, Cedrus deodara and Pinus wallichiana, with an understory of Quercus ilex and Junglus regia and scattered shrubs of Artemisia maritima and other species.

4.2.1.5 Dry Temperate Evergreen Oak Scrub

This is an intermediate zone, lying between 1,500 and 2,500 meters. The vegetation is dominated by dry oak forest (Quercus ilex). Occasionally individual stands of evergreen species are also found, including Pinus gerardiana, Pinus wallichiana, Cedrus deodara and Juniperus spp.

4.2.2 Medicinal Plants

A large number of medicinal plants grow in the natural forests of Gilgit-Baltistan, especially Astore Valley. The following is a list of important medicinal plants found in the region.

Table 4-15: Important medicinal plants report in GB Forests

	Botanical Name	Local Name		Botanical Name	Local Name
1	Aconitum chasmanthum	Mohri	12	Onasin echioides	Laljari
2	Aconitum hetrophyllum	Partis	13	Orchus-latifolia	Salib misri
3	Aconitum lavae		14	Picrohiza-kurrva	karroo
4	Angelioa glauca	Chora	15	Podophyllum-emodi	Ban kakri
5	Arterrisia bravifolia	Rund	16	Rheun emodi	Rhewand chini

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6	Carum spp.	Kala zeera	17	Sausuria-lappa	Kuth
7	Ephedra spp.	Oman (asmani booti)	18	Saxifraga ciliata	Zakhmay hayat
8	Ferula feotida	Heeng	19	Shymus serpyllum	Bannanajwainu
9	Ferula narthex	Heeng	20	Swertia chiretha	Chiretta
10	Lavatria kashmirianian	Resha Khatimi	21	Valeriana wallichii	Mushak bala
11	Macrotomia-benthami	Gao zaban	22	Viola serpans	Banafsha

4.2.3 Forestry

Forestry is important for fuel, timber, in addition to control of the soil erosion and reduction silt load in lakes and rivers. In the Gilgit-Baltistan only Diamer district is rich in forest while the other five districts including Hunza have nominal forest of Juniper. The forests consist of blue pine, spruce, willows and shrub consist of rosa species.

A new program of planting trees over private land by AKRSP and 10 billion trees tsunami in the valley has been started. The forest areas including uncultivated wasteland are State Forests owned by the government. Wood is used for timber, fire and fuel wood is used throughout the year. Firewood is used during winter season. Based on data used by AKRSP each house on average use 100monds of fire and fuel wood during a year. On the other hand, fire and fuel wood collected from common property is 63 mounds per annum. Forest trees are rich source of fodder. It was noted that 12 mounds of fodder are also collected by each household from the forest. The Region is rich in natural forest although it has been extensively exploited. In the valley more forest plots are planted to reduce the pressure on existing forest. For this purpose, an average 130 trees of Poplar by each household and 90 plants of willow per household are planted

In program of ten billion tree tsunami 4.4 Million trees were planted in 2019-20 year through Gilgit forest circle, Diamer Astore Forest Circle, Baltistan Forest Circle, Wildlife Divisions, AKRSP and through Agriculture Department in Gilgit Baltistan.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- **Proposed Plantation in Hunza District for the year 2021**

S.No	Activities	Sites	Area /KM	Total nos. of plants to be planted
1	Avenue Plantation	Nasirabad to Aliabad	45 km	30,000
2	Slope plantation	Attabad lake	700 Kanal	25,000 (first Phase)
3	Block Plantation	Hussaini	1680 Kanal	50,000 (first Phase)
4	Block Plantation	Gulkin Shahabad	948 Kanal	25,000 (first Phase)
5	Block Plantation	Khuramabad	1500 k	50,000 (first Phase)
6	Free Distribution of plants	Across Hunza District	-	150,000
7	Urban Planation	District Head Quarter	-	15,000
Total			-	**345,000**

With action plan of 10BBT, it will improve the production and procurement of forest and fruit plants, rehabilitation program of natural forest and awareness campaign for forestry will help in plantation of trees in the region. Proposed site for plantation is shown in figure.

Figure 4-3: Plantation site Khuramand & Zarabad, Hunza

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.2.4 Fauna

This diverse range of vegetation and ecological zones also supports a rich faunal diversity, including an estimated 54 species of mammals and 230 species of birds. About 23 species of reptiles and 6 of amphibians have been reported from GB. Among reptiles 9 species are of lizards and 14 of snakes, while among amphibians 2 species of frogs and 4 of toads. Very little information is available on insect diversity in GB, however, about100 species of butterflies have been reported from GB.

Several globally threatened species – including the snow leopard and Markhor – continue to survive in Gilgit-Baltistan in significant numbers. The flora and fauna belong to Palearctic region. Fifty-four species of mammals have been reported in GB, which comprise 1 shrew, 10 bats, 18 carnivores, 6 artiodactyls, 3 lagomorphs, and 16 rodents. The region is also home to a few globally threatened species like Snow Leopard, Himalayan lynx, Marco polo sheep, Blue sheep, Ladakh urial, Markhor, Musk deer, and Woolly Flying Squirrel. The resident avifauna includes Monal pheasant, Snow Partridge, Himalayan Snow Cock, and several birds of prey species.

Woolly Flying Squirrel has been reported as endemic in GB, whereas Astore Markhor (flare-horned Markhor) can be considered near endemic, as its distribution is restricted to a few valleys mainly because of rugged terrain and geographic barrier like rivers. The distribution of many small mammal species is very patchy and restricted to the certain watersheds due to the physical barriers like high mountains and rivers.

Occurrence of some rare species has been reported in GB. These include species like Lammergeyer and Golden eagle. Few sightings of Lesser Kestrel have also been reported in lower Hunza near Hunza river. The main diverse group of birds in NA is the Passeriformes species. These are mostly Warblers, Tits, Flycatchers, and Buntings. Some of the restricted range species like Snow Partridge and Himalayan Monal pheasant are extremely rare and may be at the verge of extinction from many of their earlier strongholds. According to Birdlife International (2001) report there are 27 species of Pakistan, which are threatened internationally out of which 7 species are found in GB.

Hunza is very scattered settlement with meager population. Considering its wildlife resources to be protected and preserved. Shooting, trapping of wild animals is not allowed except with a special permit. The number of animals or birds killed or captured is also restricted and specified in the permit. Snow leopard and Ibex are already declared as endangered and other species of mammal are also scarce. But trophy hunting is allowed which is beneficial to the local community as the 70% of the funds go to local community which is used for the development of the local area.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Table 4-16: Fauna available in Gilgit Baltistan

English Name	Urdu Name	Scientific Name
Ibex	Kill or Kil	Capra ibex sibirica

4.2.5 Insects

The Project Areas is rich in biodiversity of insects including butterflies found in the project area, particularly during the humid months of July and August. In addition, caterpillars, bugs, beetles, black bees, weevils, mosquitoes, ants, green aphids, codling moths, leaf miners, mitts, fruit flies, woody aphids, stray grass hoppers, leaf hoppers, mealy and woolly bugs, peach leaf curling aphids, scale insects, walnut weevils, blister mites, and dusky veined aphides are all found in the Northern Areas including the project sites.

4.2.6 Endangered, Threatened or Vulnerable Species of Fauna

The IUCN Red List of endangered, threatened and vulnerable species in the project area are Markhor (*Capra flconeri*) Snow leopard (*Unica unical*) Ladakh urial (*Ovis vignei*) Woolly flying squirrel (*Eupegaurus cinereus*.)

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.2.7 Community Controlled Hunting Areas

The concept of biodiversity conservation through community development was piloted in a few selected valleys by International Union for Conservation of Nature -IUCN under a Global Environment Facility (GEF)/ United Nations Development Programme (UNDP) project in Gilgit, Baltistan and Chitral during the period 1995-1998. The success of the project resulted in expanding the concept to a larger canvass and today there are 27 communities-controlled hunting areas. The participating communities are required to write a management plan for conservation and sustainable use and monitor the population of species targeted for trophy hunt. The major species being managed for trophy hunt are Markhor, Ibex, and Urial. The communities are issued permits by government for the number of animals that can be safely hunted. The community's sale the permits nationally and internationally through outfitters. Eighty percent of the income from successful hunt goes to local community while 20% goes to government to cover administrative costs.

In Diamer district, the local people manage wildlife through their own traditional system known as Zaitu Committee. These traditional committees exist in almost all villages/valleys of district Diamer for the sustainable management of respective natural resources. The Zaitus (conservation committee) are formed by village elders (mostly numbardars), with representation of the whole population from each Haiti (Muhallah). However, these traditional committees were reformed by Wildlife Conservation Society (WCS) as Wildlife Conservation and Social Development Organizations (WCSDOs) and have been registered under social act at respective districts offices.

4.2.8 Protected Area

In order to safeguard the biodiversity of key ecological systems, Government of Gilgit-Baltistan has declared four National Parks to protect and conserve bio-diversity of Gilgit Baltistan. These include Handarb National Park, Khunjerab National Park, Deosai National Park and Central Karakorum National Park. In the protected forest, the forest owned by Government as per Forest Act-1927, all activities are prohibited until and unless permitted by the government. Usually, removal of fallen, dying, and dead trees is not banned, however, grazing, sometimes, is regulated to ensure regeneration. In Gilgit Baltistan, designated protected forests cover an area of 445,712 ha and are mostly found in Ghizer, Astore, Skurdu and Gilgit Districts. Out of that 64,512 ha is conifer forests while 3, 81,200 ha are scrub forests (IUCN, 2003).

Aga Khan Rural Support Programme (AKRSP), International Union for Conservation of Nature (IUCN), Wildlife Conservation Society (WCS) and World Wide Fund (WWF) are the main international organizations who over the last two decades have played a crucial role in creating awareness among communities for sustainable management of biodiversity resources. The then Ministry of Environment also implemented a Program for Mountain Areas Conservation (PMAC) to promote biodiversity conservation in Gilgit Baltistan through community participation. This program was completed in 2011. As a result of these efforts the Gilgit Baltistan offers a model for community based management of forestry resources.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Despite of all these conservation initiatives and efforts by government and international organization, fast depletion of forest ecosystems has been observed in the last two decades. The following strategies and actions will be taken to achieve the objectives of conservation, sustainable use and equitable sharing of benefits.

4.2.9 CONSERVATION AND SUSTAINABLE USE OF BIODIVERSITY

The major threats to biodiversity are deforestation, degradation and fragmentation of habitats, indiscriminate hunting, wildlife-livestock competition and killing predators to control livestock losses. Out of total area of 72,496 Km^2, less than one percent (5,016 ha) area – the protected forests, is under management of the government. In addition, 216, 584 or three percent of total area is designated community forests, where except for regulating logging the government has no other role. The remaining 98% landscape is under customary control of the local communities and is used for grazing of livestock and fuel wood collection.

In order to conserve representative samples of ecosystems, and protect the threatened species, a number of protected areas have been established across the region. There are four National Parks, two game sanctuaries, and six game reserves. In addition, to recover the populations of the rapidly declining game animals, the government has introduced a sport hunting programme where local communities are encouraged to protect populations of big game and keep 80% of the permit fee. The location of protected areas is shown in figure 4.6 and an over view of the conservation and sustainable use measures follows.

- Khunjerab National Park
- Central Karakorum National Park (CKNP)
- Deosai National Park
- Qurumbar (Karambar) National Park
- Shandur-Hundrub National Park

4.2.10 GAME RESERVES

The game reserves areas set aside for conservation of key game species, however, hunting and shooting is allowed except under a special permit. There are eight game reserves in GB and an overview of the major species in the area.

Table 4-17: Game Reserves Areas

Game Reserve	Area (km^2)	Key Species
Danyore (Gilgit)	443	Markhor, ibex, Urial, snow leopard, lynx, wolf, fox, etc and bird species
Kilikmintika (Hunza Gojal)	650	Ibex, Marco polo sheep, snow leopard, brown bear, fox, marmot, etc and bird species
Nazbar Nallah (Ghizer Yasin)	334	Ibex, snow leopard, brown bear, wolf, fox, etc and bird species

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Chassi Bowster (Ghizer Phander)	370	Ibex, snow leopard, wolf, brown bear, fox, etc and bird species
Pakora (Ghizer Ishkoman)	75	Ibex, snow leopard, wolf, fox, etc and bird species
Askore Nullah Skardu	129	Ibex, snow leopard, wolf, fox, etc and bird species

4.2.11 Aquatic Ecology

Gilgit-Baltistan is blessed with highest potential of cold and clean water resources in shape of lakes, canal, reservoirs, rivers, and water logged areas that offer ideal habitat for trout and other cold water fish species. There is dire need to get maximum benefit from these resources through technological advancement in production, processing and marketing. Both the public and private sector are fully involved in order to judicially exploit this potential both in natural waters as well as its development in culture conditions.

Hunza Valley is blessed with great water resources comprised of streams and alpine lakes fed by the snowmelt and glacier waters. The fish fauna in Hunza Valley is relatively poor due to high turbidity, low water temperature and high water speed.

4.2.12 Fisheries

Fisheries department Hunza was established in the year 2012 with the core aim to develop and promote Fisheries and aquaculture activities in newly created district. District Hunza has very rich aquatic resources of aquaculture and fisheries in forms of bluish lakes, gashing rivers, torrential streams, seasonal and perennial springs etc.

District Hunza being gate way to the CPEC and hub for tourist has great potential in terms of natural recourses and well aware educated man power can contribute and play vital role in the development of the area. The scenic beauty and natural water resources of Hunza attracts a great influx of national and international tourist every year, which may directly or indirectly contribute to the economy of local people and the region.

Fisheries department Hunza has come up with novel approach and ideas to get maximum benefit from wise use and sustainable exploitation of natural resources in multiple ways with special focus on introduction and installation of cage culture system in Attabad lake under controlled environment to enhance production with stocking and multiplication of fine verities of fish in nature. At the same time, it has also been planned to promote sport fishery providing enabling environment and other related facilities for tourists and fish anglers.

For this the Attabad lake having crystal clear water offers as natural gene pool reserve, ideal for excessive multiplication and better growth of many indigenous and exotic fish species.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.2.12.1 EXOTIC FISH SPECIES OF HUNZA

i. Salmo Trutta Fario (Brown Trout)

ii. Onchorynchus Mykiss (Rainbow Trout)

4.2.12.2 INDEGENOUS FISH SPECIES

Among the 15 identified indigenous fish species in GB the following six fish species found in District Hunza:

i. Shizothorax plagiostomus

ii. Shizothorax Nasus

iii. Ptychobarbus Conirostris

iv. Triplophysa Terwasae

v. Triplophysa Yasinensis

vi. Diptychus Maculatus

4.3 SOCIAL AND ECONOMIC ENVIRONMENT

4.3.1 Population

The population in Gojal consists of 51% male and 49 % female; it has a population density of 17 persons/acre. The child-women ratio of the study area is 345 children per 1000 women. The dependency ratio is 142 % in Hunza Valley, which shows that there are about 3 dependents on every two earning members. The average size of household is 7.26 persons. The average size of family is 7 persons per household, while the density of room is 4 rooms per household.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

In the study area of Gulmit, Shishkat and and Passu total number of households according to the census 2017 is 8697 people, these are the areas surrounding the Attabad village. The detail of population is shown in table

4.3.2 Languages

Burushasky and Wakhi are the main languages of Hunza Valley. There are some other languages in the region as well which are described below:

- **Shina**. Shina is the main language in Gilgit. It is spoken in the Gilgit, Diamer, Ghizer and Astore. Shina speaking people are further found north in the Ishkoman valley and in Hunza, Nagar and further east in Baltistan.
- **Burushasky.** Burushaski is the main language of Hunza valley. It is spoken by the people settled on either sides of the middle cause of the Hunza River, on its northern bank (Hunza) as well as on its southern bank (Nagar). There are also Hunza speaking settlements in Yasin and in Gilgit. Burushasky is still an unwritten language.
- **Khowar.** It is the main language of Chitral, however Khowar speakers may be found in Yasin. Marriage ties make Khowar understood in Gilgit in some families.
- **Balti.** Balti is the sector largest language in the Baltistan Division. It is mainly spoken in the two districts of Baltistan division. Balti peaking people are settled in Skardu, Rondu, Shigar, Khapolu, Kharmang, Gultari and Ganche.
- **Domaaki.** Domaaki is the language of the Domas of Berichos who are also found in Gilgit and in some Shina speaking villages of the lower Hunza valley. They are mainly musicians and smiths.
- **Wakhi.** Wakhi is spoken in Ishkoman valley and in upper Hunza valley by more than 3,000 people. It belongs to the Pamirian branch of Iranian languages.
- **Gojri.** Gojri is the language of Gojar family settled in Naltar valley, Karga and also in the surrounding areas of Gilgit.

4.3.3 Ethnic Groups and Religions

Almost, 95% of the people living in Hunza valley and 100% in Upper Hunza belong to Ismaili faction with The His Highness Prince Karim Aga Khan as their spiritual leader. 5% in Hunza Valley are members of Shia Imami faction which is concentrated in the village Ganish and surrounding settlements.

4.3.4 Administrative Setup

Hunza remained an independent state after 1947 while still staying under the control of the Islamic Republic of Pakistan. The last Mir (Jamal Khan) and his family were retired and the Mirdom was abolished, and Hunza became a subdivision of the Northern Area in 1974. The government tried to establish administrative structure in the valley. The abolition of the traditional institutions left a gap that was partly filled by institutions established under projects of the Aga Khan Development Net Work (AKDN), which started operation in 1979.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.3.5 Aga Khan Development Network (AKDN)

After the annexation of Hunza and the abolition of the principal state a space concerning rule, law, administration and organization was created. It took a long time for the government institutions to fill this gap. AKDN is an international network and as part of Aga Khan Foundation (AKF) deals with issues such as education, rural development, culture, health services, housing programs and quite a few others. With its headquarters in Geneva and having been founded in 1967, The AKF is an international agency for development co-operation. Within the sub-branches of the AKDN, the Aga Khan Rural Support Program (AKRSP) is for rural development. The activities of the AKDN have shaped the development of the valley extraordinarily. Its various offices provide jobs for higher qualified Hunza cuts when they return from their studies in down country. Employment is also provided in the public sector in the rural areas. The AKDN extends its activities to establishing healthcare facilities and educational institutions.

The AKRSP was established in Gilgit and covers 84% of the household in Gilgit-Baltistan. The AKRSP started supporting institutional development on the local level in 1982 by establishing community-based organizations (CBOs) like Village Organizations (VO) and Women Organizations (WO). These associations were established all over Hunza within a few years. It initiated developmental projects in this area aiming at improvement of the condition of the rural population and providing basic facilities to the masses, with special emphasis on infrastructure.

4.3.6 Housing Characteristics

People in Gojal valley are very traditional about the situation of their households. Settlements are located in the center of the village and agriculture area surrounded it. The center still remains the center but the settlement is now of dispersed type, with the houses being sited on the individual fields. The area also remained safe and secure, and therefore the people did not find it necessary to cluster their houses together in selected sites. Thus the houses are scattered throughout the village from one end to the other end.

The Wakhi house type is a combination of all human activities in one open connected space. The whole structure is erected on five central pillars to support the roof. The fireplace is in the middle of the floor. The different functions of houses are located around the central fireplace (buxari). The house has a lantern place at the ceiling. Almost all the houses in the valley have the facilities of electricity.

4.3.7 Health Facilities and Common Diseases

The villages in the Hunza Valley have somewhat better healthcare facilities than rest of the GB except Gilgit and Skardu. Aga Khan Health Service (AKHS) and Government health workers are providing health facilities in the area. They provide first aid facilities and also give family planning guidance to the people. Gulmit Government hospital was established in 1980.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.3.8 Education and Literacy

Almost all the settlements in Hunza Valley have a high literacy rate. There was no school before 1946 in the villages of Gojal. Diamond Jubilee School for Boys was established in the Gulmit on the occasion of the Diamond Jubilee Ceremony of Sir Sultan Mohmmad Shah, Aga Khan III in 1946. At present there is one Government High School for Boys and one D. J. High School for Girls, besides one public high school: Al-Amin Model School for boys and girls. There are two primary schools in Hussaini village. Literacy rate in Hunza is almost 95% which is higher than other districts of GB. Girls in Hunza are enthusiastic about their future so they prefer to have higher education. For higher education students go to KIU Hunza Campus in central Hunza; a number of boys and girls are studying in Gilgit, Islamabad, Peshawar, Lahore, and Karachi for higher studies.

4.3.9 Infrastructure and Recreation

Infrastructure facilities including health, education and transportation are available in Hunza Valley to those near the KKH. Construction of Karakoram Highway (KKH), the Silk route or Pak China Friendship Highway, was started in 1965 and was completed in 1986. The KKH starts from Thakot in KPK and continues up to Khunjerab Pass; it has over one hundred bridges. The length of KKH is 1300 km and width is two lanes. KKH has played an important role in the development of Hunza Valley. Buses and vans are used for traveling in Gojal from and to Gilgit and down areas of the country. Public transport is provided by both Private vans and Government buses (NATCO).

The impact of the Karakoram Highway is very conspicuous on the socio-economic condition of the villages. Karakoram Highway provides an important link between Pakistan and China. This road serves the tourist traffic and acts as supply route for the mountaineers to the down country and other neighboring countries.

Recreation and tourism has grown in the area rapidly, which in future can become an important source of income. Impact on literacy rate is also becoming obvious with the fact that on the one hand more educational institutions are being opened.

4.3.10 Professions and Source of Income

The people of the area are linked with different professions like tourism sector, business, livestock, dry fruits, trade and government jobs.

4.3.11 Social Organizations and NGO Involvement

NGOs have also been very active in the water sector. Aga Khan Rural Support Programme (AKRSP) has accorded high priority to the Northern Areas' irrigation systems and water supplies from its inception; AKRSP also pioneered the creation of Water Users' Organizations (WUOs), which now play a pivotal role in all village-level, water-related activities. With the technical assistance of Aga Khan Cultural Service Pakistan (AKCSP), the Karimabad Town Management Society has been involved in the development of a new sewerage system for the town of Karimabad.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4.3.12 Tourism and Cultural Heritage

Hunza is the tourism and business hub of Gilgit-Baltistan thus a large number of residents from this area directly or indirectly involves either in business or work in tourism sector.

4.3.13 Status of Women

Women are empowered in Hunza Valley and receive primary as well as secondary level education, while those having education limited to intermediate go in for teaching thus making primary female teachers available locally. Moreover, male as well female students from each village in the Gojal tehsil are studying outside Gojal and also abroad and more preparing to leave in the near future, women and girls have to take up what the men and boys were supposed to do.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5 ESIA AND MITIGATION MEASURES

5.1 GENERAL

Determining the significance of impacts identified is one of the main purposes of an ESIA and it enables the identification of necessary mitigation and a determination of environmental and social costs associated with the Project. Environmental and social impacts of any project are identified taking into account all phases of the project cycle, including planning, construction, operation and decommissioning. The environmental issues and impacts of a project depend upon the nature of the project activities, and the types and extent of interventions involved. It is not easy to predict the future and assign a relative value or overall significance to an impact, since every impact has a different and multi-dimensional nature, and also because it involves personal and subjective judgment for many attributes. An environmental or social impact can be either beneficial or adverse and is assessed by comparing the quality of the existing environment with the predicted quality of the environment once the project is in place. This ESIA identifies the impacts likely to arise as a result of construction and operational activities and assesses the likely magnitude of the impact in order to provide some indication as to which impacts are likely to be most significant. The impact assessment has been based on that environmental checklist developed by the Asian Development Bank (ADB).

5.2 IMPACT ASSESSMENT PROCEDURE

In order to describe the significance of an impact it is important to distinguish between two concepts: sensitivity and magnitude. As far as possible the sensitivity and magnitude of the impact are described with reference to legal requirements, accepted scientific standards or accepted impact assessment practice, and/or social acceptability. Where no known published ‘standard’ criteria exist for determining the magnitude of effects, established professional criteria and best practice techniques are used and clearly described.

5.2.1 Sensitivity

Sensitivity is generally site specific and criteria are developed from baseline conditions. The sensitivity of a receptor is determined based on review of the population (proximity/ numbers/vulnerability), presence of biological features of the site or the surrounding area, soil, agricultural suitability, geology and geomorphology, existing air quality, presence of any architectural and historic heritage, landscape etc. Sensitivity, relates to the value, importance and tolerance of an environmental resource or receptor and should take into account where possible stakeholders views and public acceptability. Sensitivity can be categorized as high, medium, low, and negligible to the assessment of receptor sensitivity.

5.2.2 Magnitude

The assessment of magnitude is undertaken in two steps. Firstly, the key issues associated with the project are categorized as being either adverse or beneficial. Secondly, beneficial and

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

adverse impacts are then further subdivided into major, moderate, minor or negligible based on consideration of the parameters listed below:

- duration of the impact
- spatial extent of the impact
- reversibility
- likelihood; and
- legal standards and established professional criteria.

In order to make the report as meaningful and useful as possible, an attempt has been made to describe each impact in the following terms: positive impacts refer to beneficial effects and negative impacts refer to harmful effects on e.g. natural resources, human beings and economy.

5.3 IMPACTS DURING CONSTRUCTION

During the construction phase of the project most of the impacts identified are of a negative nature but some of them will be temporary and will vanish with the completion of project.

5.3.1 Impacts on Topography

Topographically, the study area (consisting of a major part of the Hunza Valley), is characterized by steep slopes and narrow valleys. Attabad situated on the outside bend of the Hunza River bed is one of the smaller villages of the Hunza Valley and was located in a rough pastoral environment surrounded by natural slopes with sparse vegetation.

The interventions of the Attabad Lake HPP are not likely to impact the topography of the area on a large scale except for those areas where the physical activities of excavation, digging and movement of heavy machinery will take place. Similarly, areas where excavated material from tunnels will be disposed, dumped or stored will be negatively affected. This impact can be considered as a negative impact with moderate magnitude.

Mitigation

To reduce the negative impacts of excavated material: firstly, the emphasis should be to reduce the volume of material requiring disposal and, secondly, to dispose it in environmentally friendly way. The following measures are proposed in this respect:

- As far as disposal on the dam site area is concerned, some of the spoil can be used for construction project related structures.

- To make the dam site easily accessible for movement of heavy machinery and for large number of vehicles (per hour/per day), it will be necessary to improve, upgrade and widen the roads. Some of the spoil can be used for widening of the roads.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Part of the excavated material on the powerhouse site can be used for making aggregate required for project construction and for the development of infrastructure such as roads and filling of natural depressions.

5.3.2 Impact on Seismicity

The area is well known to consist of active landslide zones as more than 33 damaging events have occurred in the region during the period from the year 1830 till January 2010 (Kreutzmann 1994). In addition to this, according to the Geological Survey of Pakistan (GSP) a fault line also passes through the area. During the devastating 2002 earthquake in Astore that also hit Attabad, the process of crack evolution in the mountains of Attabad region was observed, which worsened during the subsequent strong earthquake (7.5 on Richter scale) in 2005. With the passage of time, cracks began to widen slowly and gradually on January 4, 2010, slope failure occurred in the Attabad region resulting in the establishment of a natural dam that completely blocked the Hunza River. According to the initial estimates, a slide mass of approximately 30 million m_3 fell from the northern valley wall.

Mitigation

All structures to be built must be designed giving maximum allowance to seismic factors. A very careful analysis of the situation will be required during the design stage of the project by specialist consultants.

5.3.3 Impact on Geology

Almost all project interventions involve excavation of natural rocks, cutting of formations, moving and dumping of spoil. During tunnel excavation and some other operations, blasting of the formation will be required. All these activities will disturb the existing geological formations and consequently physical features of the local geological formations of the project area will be damaged at some places, which is a negative impact of moderate magnitude.

Mitigation

All these activities are an integral part of the project interventions and cannot be avoided. Blasting should be minimized where possible (near the surface) and, if unavoidable, low power explosive should be used and a greater number of blasts with low power material may be preferred instead of high intensity single blasting.

5.3.4 Impacts on Landslides

As the natural dam had been a result of a major landslide, therefore, special emphasis should be given to this aspect. Landslides are common in the project area due to the high steepness, unstable geological formations on both sides of the river and common seismic activities. Due to the project activities, especially blasting of rocks in some areas, the formation will become loose and the risk of landslides will increase in the immediate vicinity of the construction sites

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

specially at the right bank of Hunza River, which may be considered as a moderate negative impact of the project.

Mitigation

To avoid the major risks, all structures are proposed on the left bank of Hunza River. Further, to minimize blasting of formations and, if unavoidable, then use low intensity explosive if possible.

5.3.5 Impacts on Land Use

There will be no major impacts on the land use of the area as the lake has already been formed and changes has already been taken place long before this project. However, new infrastructure will be built in the area which would have positive impacts on the land use.

5.3.6 Impacts of Excavated Material

It is planned to excavate a 5.3 m diameter headrace tunnel 2.1 km long from the weir site to the powerhouse, one diversion channel and one tailrace tunnel. Excavated spoil material will require dumping at both ends of the tunnels near the dam and near the powerhouse. Unplanned disposal may create environmental degradation of the area and environmental issues of significant adverse impacts can emerge during construction of the project. The nuisance created by excavated material will be a moderate negative impact of the project.

Mitigation

Same mitigation measures as of Section 5.3.1.

5.3.7 Impacts on Infrastructure

As there would be no resettlement involved in the project, therefore, impacts on infrastructure would be rather positive.

5.3.8 Impact on Climate

Project construction involves large scale activities including the movement of different types of light and heavy traffic, working of heavy machinery, blasting of rocks, operation of batching and mixing plants and the presence of large numbers of people in the area. Due to all these activities, it is expected that the microclimate of the project area (surrounding the dam site and powerhouse site) will suffer significantly. However, no impact on climate of the whole project area is expected, either positive or negative, during the construction phase.

Mitigation

The deterioration in the local climate during the construction phase will be of a temporary nature and will disappear with the completion of the project. However, some measures to minimize the impacts on air quality mentioned are as under:

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- Use of new and good condition old vehicles which emit less quantity of smoke.
- Regular tuning and maintenance of vehicles and other machinery.
- Avoid blasting to the maximum level but where necessary make the moderate intensity blasting instead of heavy intensity and blasting must be during daytime.

5.3.9 Impacts on Hydrology

During the construction stage, there will be no changes in the hydrology of the river. The flow from the reservoir will be diverted to downstream of the weir through diversion channel. The adverse impact may be considered as of negligible magnitude.

Mitigation

No mitigation is required as impact is very minor in nature.

5.3.10 Impacts on Surface Water

During the construction stage, no impact on quantity and quality of the surface water is envisaged as entire water in the river will be diverted from the reservoir to the river from the diversion channel.

Mitigation

No mitigation is required.

5.3.11 Impacts on Sedimentation

During the construction stage, the overall sedimentation rate will remain almost the same up to the dam site, but it may change because of movement of heavy traffic, dumping of the excavated material and other project related activities. The impact is considered as negative but of short duration and of minor magnitude.

Mitigation

This impact is unavoidable due to the nature associated with project activities, which will disappear with the completion of the project.

5.3.12 Impacts on Flooding

Flooding of the river at the dam site is not a common feature although some floods of high intensity are recorded in the past e.g. the glacial lake outburst floods of 1929. As river water from the upper cofferdam will be passed through diversion channels, there is chance that these tunnels could not accommodate the flows in any abnormal year. In such cases, floodwater can overtop or breach the cofferdam and damage the partially constructed civil works and lower cofferdam. The impact can be considered as significant positive impact.

Mitigation

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

The diversion tunnels must be designed to pass maximum flow of the river and height of the upper cofferdam should be fixed keeping in view the historic flood height at dam site.

5.3.13 Impacts on Groundwater

During construction stage, no impact on groundwater is envisaged as the flow of water will continue as such without any storage.

5.3.14 Impacts on Air Quality

The project activities during construction at both weir and powerhouse sites will involve large movements of heavy diesel operated machinery and vehicles which produce more noise and generally emit more smoke. Similarly, various levels of noise and air pollution are expected to be generated from construction machinery and equipment, working of heavy earth moving machinery, drilling, blasting operations, concrete mixing, pouring equipment and stone crushers etc. The impact on air quality is considered as short duration negative impact of moderate magnitude.

Mitigation

All sources of air quality deterioration will be for short duration, temporary in nature and associated with project construction activities, which will end with the completion of the project. The contractors and sub-contractors must be held responsible through special clauses in the tender documents to strictly follow precautionary measures.

5.3.15 Impacts on Agriculture and Vegetation

Agriculture in the project area is practiced on a limited scale on scattered flat patches and on contour strips developed by the farmers with their own efforts and resources. The main source of irrigation in the area is the snow melt water diverted from streams towards crops, orchards and fields. No irrigation is practiced from river water in any part of the project and no impact on agriculture is expected during the construction phase of the project.

5.3.16 Impacts on Terrestrial Flora

The project area has very thin vegetation cover due to the special features of the terrain i.e. poor rainfall and steep mountains with very little soil cover. During construction stage, the damages to flora can be done by vehicles and machinery, establishment of camps and permanent structures etc.

Mitigation

Dumping of construction materials should be avoided where large number of terrestrial trees, shrubs, herbs, grasses and fruit trees are found.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5.3.17 Impact on Terrestrial Fauna

Construction activities will generate moderate to major impacts to Fauna within the project area in particular at the powerhouse, dam site, tunnel route and quarrying areas. Blasting and tunneling in particular will cause loud shocks and vibrations that are likely to affect habitats and wildlife in surrounding of the project area. The ability of wildlife species to move out of construction areas will depend on the availability of suitable alternative habitats, access to those habitats, and rapid mobility required to avoid construction clearance activities. Sometimes some mammals come down from the uplands in search of food. Construction activities will disturb the migratory route of mammal species, however, this will be a minor impact.

Overall, the construction activities will generate impacts of negative nature on all types of fauna but of moderate magnitude.

Mitigation

Almost all impacts will be of a temporary nature, which will end with completion of the project. Dumping of construction materials should be avoided in areas where mammals, amphibians, reptiles and birds settle.

5.3.18 Impacts on Aquatic Life

During the construction phase, very nominal impact on aquatic life is expected as there will be no change in flow patterns in the river. The impact can be taken as of negligible magnitude.

5.3.19 Involuntary Resettlement

There is no displacement involved for the project, thus, no resettlement will be taken place.

5.3.20 Impacts on Employment Opportunities

At present employment opportunities in the project area are limited to few fields which would increase with the construction activities. Majority of local employees will be engaged in the unskilled and semi-skilled sectors. Employment generation impacts during the construction period are to be considered as major positive impact of the project.

Enhancement

The contractors of the project components shall be bound legally through contract agreements to engage 100% unskilled labor from project area / Gilgit-Baltistan. Preference should also be given to local skilled and semi-skilled manpower if available.

5.3.21 Impacts on Regional Safety and Health

People of Hunza are used to interact with people from different areas, cultures and communities. However, when there is sudden influx and congestion of people at any place from other areas for a longer period of time, it may contribute to adverse effects on the community health, safety

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

and security of locals. There is always potential for such social impacts as incidences of accidents, social conflicts, theft and spread of communicable diseases.

Mitigation

The contractors must be bound to establish workers camps sufficiently away from the settlements of local people. During construction, the project working sites need to be bordered by a fence to safeguard life and property. As appropriate, any warning signs related to safety and security should be displayed in local languages. An appropriate security system must be in place to control all access routes to the site.

5.3.22 Impacts on Occupational Health and Safety

There is a tendency for the construction sector to be unregulated with respect to occupational health and safety. Additionally, unskilled and even some skilled construction workers may be illiterate and not necessarily informed or familiar with the protective measures to be adopted during work.

Mitigation

The contractors will need to carry out risk assessments and then develop site and project specific Health and Safety Management Plans to prevent accidents, injuries and work-related diseases.

5.3.23 Impacts on Resources

Construction workers will need their daily supplies in the project area. This could potentially negatively affect the existing resource base and cost for firewood, food, goods, water and fish as well as create considerable amounts of waste. Both community members and construction workers will be affected by resource constraints and changing prices and are considered sensitive socio-economic receptors, because of their limited purchasing power and state of poverty which could be affected by these impacts. These impacts are considered to be negative and of minor magnitude.

Mitigation

Mitigation measures will be needed to ensure that the project site is managed in a manner that is socially responsible and reflect sound environmental management practices. With respect to resource use, the Contractors will be expected to develop a plan and budget for providing workers with fuel for cooking and heating, water for cooking and cleaning, food supplies, and hygienic sanitation facilities for collecting and disposing rubbish, including construction waste.

5.3.24 Impact on Roads Traffic

The project area is approachable only through KKH which is also used for trade purposes with China, however, some weir and tier will be occurred with the movement of heavy traffic. This impact is one of the minor negative impacts of the project.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

Mitigation

Care must be exercised for the safe transport of raw materials and the transport and disposal of waste. Project vehicles and equipment will be maintained properly and project related traffic will be required, as a minimum, to travel at not more than the speed limit.

5.3.25 Impacts on Communication

The existing local roads network of the area is very poor. During construction, a number of additional local access roads and bridges will be required to facilitate construction works. The proposed location for the headrace tunnel is currently not properly accessible at the weir site on left side of the river and will require repair. Impacts of the enhanced road network and improved communication facilities in the project area are considered to be a major positive impact of the project as local inhabitants will also use the same infrastructure.

Mitigation

No mitigation is required as impacts are positive in nature.

5.3.26 Impacts on Cultural Heritage and Archaeology

No site of archaeological and historical importance has been identified in the project site. Some carving on stones were found near the powerhouse site regarding the incident of 2010 landslide but these carvings are outside the project construction area.

Mitigation

Appropriate community relations have to be maintained for social respect between the local people and labor coming from other parts of the country.

5.3.27 Impacts on Tourism

The Gilgit Baltistan areas of Pakistan cover 72,496 km² and possess one of the most rugged landscapes on earth and about 101 peaks above El 7,000 m. Hunza has even a special place in GB itself and every year hundreds of local and foreign tourists move into the area particularly during the summer. During the construction phase of the project no impact of any positive or negative nature is expected.

5.3.28 Impacts on Women and Indigenous People

Construction of the project may affect access of local people to their traditional migratory routes, and may reduce safe passage not only for the people but also for their animal herds.

Mitigation

The impacts described above will occur during the construction period and are reversible once the project is complete. Efforts shall be made by the contractor to inform and consult the leaders

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

and elders of the community about the project, especially regarding mobility and access through the construction areas.

5.4 IMPACTS DURING OPERATIONAL STAGE

During the operation phase, most of the impacts of the project on the environment of the area will be of a positive nature and negative impacts will be much less as compared to the construction phase.

5.4.1 Impact on Seismicity

The project area is considered as part of a seismically active zone. The construction of large structures may enhance seismic activity in the area which can adversely affect the weir structure, headrace tunnel, diversion channel and other structures as well as public and private property besides the loss of human life.

Mitigation

As the project is situated in an active seismic zone, continuous monitoring of the behavior of faults will be required during the operation stage and contingency plans to deal with such a situation must be part of the project management. Instruments to monitor seismic activity must be installed at the time of construction.

5.4.2 Impacts on Geology

During operation of the project the seepage from the reservoir will significantly impact the geology of the area. The seepage water will saturate the formation below and along the reservoir and soluble minerals from the rocks will dissolve in the water. Some solution channels may develop in the formation making the formation more pervious.

Mitigation

It is difficult to check or reduce the seepage from the reservoir. A continuous monitoring system will be required during operation of the project to monitor the changes in groundwater level and chemistry of ground water.

5.4.3 Impacts on Landslides

It is expected that landslides could increase due to construction activities. Further the seepage of water will make the formation loose and unstable and the chances of sliding due to rainfall, abnormally high and low temperatures and due to seismic activities will increase. The sloughing and slippage of saturated formation during regular flushing of the reservoir may also enhance the sliding potential of the area. This impact may be considered as a major negative impact.

Mitigation

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

As no mitigation is possible to check either the seepage or any resulting landslide, however, as after a few years of project operation most of the rocks along the weir site will become stable.

5.4.4 Impacts on Land Use

After construction and during the operation phase, some positive changes in land use are expected as areas under construction camps and other auxiliary services will revert to their pre-project use.

5.4.5 Impacts of Dismantling Material

After completion of the project construction but before operation of the project, temporary structures, batching and mixing plants and labor camps etc. will require dismantling and a large quantity of spoil material will become available for proper disposal, which will be a moderate level negative impact of the project. The debris produced will require proper dumping or disposal to avoid any environmental degradation. This spoil will pose a moderate negative threat to the environment.

Mitigation

There are places in this length near powerhouse site where spoil can be dumped without producing any adverse impact.

5.4.6 Impacts on Infrastructure

The construction at powerhouse site will disturb the supply line of goods and services for people living on the right side of the river at Sarat Village, however, enough space is available at the powerhouse site for the movement of locals. The impact is considered as a moderate negative impact of the project.

Mitigation

Proper boundary shall be marked by the contractor at the construction sites to facilitate the locals.

5.4.7 Impacts on Climate

The lake has already been there since 2010, therefore, no major changes would occur to the climate after the project has been completed.

5.4.8 Impacts on Hydrology

During the operation stage, there will be no changes in the hydrology of the river. Flushing will be carried out regularly and no special annual flushing will be needed, therefore, no changes would take place on hydrology of Hunza River, moreover, 3 m^3/s environmental flows will be released, at least, to downstream of the weir for the aquatic life during operation.

Mitigation

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

To conserve the aquatic life (flora and fauna) of the river downstream of the weir (2 km patch), minimum flow of 3 m³/s has been calculated as the environmental flow. It will be obligatory for project operating agency to release 3 m³/s in the river throughout the year as environmental flow.

5.4.9 Impacts on Surface Water

The capacity of the reservoir at El 2,409 m.a.s.l is calculated as 125 Mm³, which is very small compared to inflows. As the Attabad Lake HPP is a run-of-river power project, with the implementation of the project there is no chance of reduction of discharge in the river except in the section between weir and end of tailrace (2 km). Presently, in this section of the river, water is not being used for any purposes either for human consumption or for agriculture. Therefore, it is anticipated that there will be no impact on human population due to the diversion of discharge into the tunnel.

Mitigation

Environmental flows must be ensured to maintain the surface water hydrology of the Hunza River.

5.4.10 Impacts on Sedimentation

The Hunza river water always contains huge sediments of around 20-21 Million Tons annually on average. Diversion Channel will be used for flushing of sediments during high flow months. It is expected that release of sediments in moderate quantity could change the morphology of the river below the dam. However, as sediments will be released during high flow months with relatively high velocity of water and the river in this section has a high gradient, it is expected that sediment will move far away from the downstream of the weir site.

Mitigation

The silt clearance (flushing) mechanism has been provided in the project design through channel/sluices. It is proposed to flush the reservoir regularly during high flow months.

5.4.11 Impacts on Flooding

Flooding of the Hunza River at the weir site is not a common feature although some floods of high intensity have been recorded in the past at upstream site e.g. the glacial lake outburst floods (GLOF) at Shimshal River. As river water will pass through the headrace tunnel and overflow spillways, there is a chance that these tunnel and spillways could not accommodate the flows in abnormal years, which may pose a threat to the main structures and this impact can be treated as major negative threat.

Mitigation

The design of the weir has considered the design flood of 1 in 10,000-year flood of 3,250 m³/s.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5.4.12 Impacts on Groundwater

The lake has already been formed, therefore, there will be no change to the groundwater.

Mitigation

No mitigation measures are required.

5.4.13 Impacts on Air Quality

Ambient air quality of microenvironment i.e. at Sarat and Salmanabad Villages would be raised, though, slightly during the construction and reconstruction activities. Fugitive dust emission from discharge of mining waste would result from tunnel excavation. This waste will have to be suitably disposed-of, or else it would add to the sediment load that will be carried by the river.

5.4.14 Impacts on Agriculture and Terrestrial Vegetation

Agriculture in the project area is practiced on a limited scale on scattered flat patches and on contour strips developed by the farmers with their own efforts and resources. The main source of irrigation in the area is the snow melt water diverted from streams towards crops and orchards and no irrigation is practiced from river water in any part of the project, and no major impact on agriculture is expected in the project area with the implementation of the project.

5.4.15 Impacts on Flora and Fauna

There would be no significant impacts on Flora and Fauna of the microenvironment of the area during operation stage.

5.4.16 Aquatic Life and Fish Stocks

5.4.16.1 Habitat Destruction

During construction and operational phases of 54 MW hydropower project cutting, blasting, excavation, drilling, extraction, removing and dumping activities of materials at large scale contribute heavy sedimentation and soil erosion which may cause habitat damage, loss of vegetation, contamination and toxic accumulation of waste not only at Attabad lake but its impact can be seen downstream of the river as well. This situation can contribute up to great extent to destruct the aquatic life, ecology, breeding and spawning grounds of fishes, benthic fauna, food chain and abundance of micro and macro living organisms. This may lead rapid shortage of food like benthic population, phytoplankton, zooplankton, nekton etc which play an important role to sustain food chain with different trophic level in any eco-system.

Fisheries Department of Hunza has introduced several thousand fingerlings of exotic fish species namely Salmo Trutta Fario (Brown Trout) at Attabad Lake and downstream river during the period from 2012 to date for propagation and the said specie has made breeding grounds at Attabad Lake and downstream as well. Besides this a number of indigenous fish species also exist in the same water bodies having commercial as well as ecological importance.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5.4.16.2 Water Pollution

Heavy machinery and equipment will be used during construction and operational phases of the project with huge quantity of explosives for blasting of rocks. Resultantly heaps of leftovers of explosives, grease, chemicals, lubricants, and other harmful materials will be produced on daily basis. These pollutants through run off rain water enter into the lake and river course increase toxicity of water causing rapid destruction of fish population and riverine ecology.

5.4.16.3 Fish Migration

Fish usually migrate from one place to another for search of food, shelter and spawning/breeding. Due to construction of the project fish migration might be affect up to some extent.

Mitigation

- Rapid mechanism of dispose-off of such kinds of hazardous materials will be required on urgency basis by dumping the extracted hazardous materials selecting safe landfill areas away from the main river course and its watershed, so that contaminated water in form of runoff could not enter directly into the main course.
- Land sliding and soil erosion are also the main factor to contribute silt load on river bed manifold causing damage to resting and nesting grounds of fishes. Construction of protective walls and gabions at certain points to make sure the stoppage of sliding debris. Plantation and vegetation cover can also be helpful for slope stabilization. Plants, herbs and sharbs reduce the level of pollution and toxicity at a great extent as bio-filter and carbon suckers.
- Fish ladder shall be insured for freely movement of fishes.
- Fish screening system should be developed so that fish may not be trap at intake, penstock pipe or channel.
- Sewage water treatment discharged from all labour camps and toilet facilities must be treated before disposal into the river.
- Tanks of fuel, oil and other liquids to be placed quite distant from any water body.
- Washing of vehicles or other machinery in the river or nallahs to be strictly prohibited.
- Oil changes for engines and other machinery to be only allowed in workshops.
- All vehicle and machinery to be maintained properly in order to avoid any leakages.

5.4.17 Impacts on Power

The most significant impact of the project will be the power generation as the region is presently facing acute shortage of power. The power generating capacity of the project is estimated as 54 MW, which is enough to remove the power shortage from the area. The power generated will help to establish new industries, to boost commercial activities and to enhance job opportunities

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

in the valley. Electricity generation impacts are considered to be most significant positive impact of the project.

5.4.18 Impacts on Employment Opportunities

During operation stage, a large number of both skilled and semi- skilled manpower will be required, who will be recruited from the local area. Employment generation during the operation phase is considered to be of a major positive nature.

5.4.19 Impacts on Social Services

Access roads and basic infrastructure will be built as part of the project and will facilitate the access for people to goods and services. After completion of the project, these facilities and infrastructure will be available to the general public of nearby villages. The impact of better communication and other social services is considered to be a moderate positive impact of the project.

5.4.20 Impacts on Tourism, Landscaping and Visual Amenity

The Northern Areas of Pakistan cover 72,496 km² and possess one of the most rugged landscapes on earth and about 101 peaks above El 7,000 m. Every year hundreds of tourists (local and foreign) visit the area particularly during the summer.

Hunza is known for their outstanding natural beauty, high peaks and landscape and it is a popular destination among tourists from both Pakistan and abroad. The area offers tourists opportunities for outdoor activities such as hiking, fishing and trophy hunting. Impact relating to recreation activities is considered to be moderately positive.

5.4.21 Impact on Women

Contrary to the construction phase, there will be much less movement of vehicles as well as people in the area during the operation phase. Thus during this phase no negative impacts on women are expected.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6 ENVIRONMENTAL MANAGEMENT AND MONITORING PLAN

6.1 OBJECTIVES OF ENVIRONMENTAL MANAGEMENT AND MONITORING

This section of the ESIA report provides an overall approach for managing and monitoring the environmental and social issues raised by the construction and operation of the Attabad Lake Hydropower Project. The objective is to provide an overall framework for implementing the mitigation measures that adequately address the identified adverse impacts and also the enhancements for predicted positive impacts. In addition, the items that require monitoring of the environment are also identified. All of these measures are to be put into a coherent Environmental Management and Monitoring Plan (EMMP), complete with the institutional arrangements and resources required to successfully implement the required actions.

The main objectives of an EMMP are as under:

- Provide the details of the project impacts, along with the proposed mitigation and enhancement measures.
- Define the roles and responsibilities of the project stakeholders, including the project proponent, contractor, supervisory consultants and other key players.
- Identify the training requirements needed for the key role players in order for them to effectively implement the EMMP.
- Provide a mechanism in the form of an environmental monitoring program, that outlines which key parameters (both for the natural and social environment) will need to be monitored and the frequency that each of these has to be carried out.
- The objective is to ensure that mitigation measures are being effective in keeping environmental conditions within prescribed limits and if they are not, then making sure that there is an effective response mechanism that allows corrective action to be implemented.

6.2 MITIGATION MANAGEMENT MATRIX

The Mitigation Management Matrix (MMM), a preliminary outline is considered to be one of the main elements of the EMMP. The MMM shall be prepared during detailed design keeping in view the required functions and responsibilities and is to be used as the management tool for the implementation of mitigation measures. The mitigation management matrix should include:

- The required mitigation measures recommended in the ESIA report.
- Identification of the person or institution/organization directly responsible for adhering to or executing the required mitigation measures.
- The person or institution/organization responsible for ensuring and monitoring adherence to the mitigation measures.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

- The parameters that will be monitored to ensure compliance with environmental standards and also with the requirements and objectives of the mitigation measures.
- The timing at which the mitigation or monitoring has to be carried out.

6.3 MANAGEMENT OF DIRECT CONSTRUCTION IMPACTS

Construction programs and management of construction impacts shall be included by drafting appropriate environmental management clauses into the construction contracts. Once a master checklist of direct construction impact issues has been finalized then a monitoring checklist can be created for use by the supervising engineers during the construction period. It is crucial to clearly define the responsibilities of each of the parties in the construction works (contractors, supervisors and the project proponent).

6.4 SITE RESTORATION PLAN

The main areas that will require site restoration include the main construction site area, workers' accommodation sites, land used for vehicle and material workshops and stores along with material excavation and storage areas and temporary access roads and tracks. These areas will need to be restored to their original condition as far is possible and where there has been significant change then landscaped to fit with the surrounding area. The restoration work includes the removal of all temporary construction works and materials, followed by the landscaping and planting of the areas, including provision of adequate surface drainage to ensure that there will be no erosion and particularly sedimentation into the reservoir. The following procedures will be adopted for the restoration of the site:

- All temporary constructions built for the site development will be removed.
- Areas used for construction camps will be restored to their previous condition as far as is possible and where this is not then appropriately landscaped and planted to an agreed plan.
- All toxic and hazardous chemicals and materials will be totally removed from the site followed by treatment and environmentally appropriate disposal.
- During the construction program efforts will be made to minimize the risk of oil and chemical spills and an effective clean-up program should be in place to remove these as soon as they happen.
- All debris from construction activities should be removed from the site and appropriately separated, reused, recycled and composted with the residual material appropriately incinerated.
- All redundant fencing and gates will be removed and excavated pits will be appropriately backfilled.

6.5 RESERVOIR MANAGEMENT PLAN

Reservoir area will need to be managed during both the construction and operation of the project. The risk of debris entering the intakes also has to be considered. Once a clear idea of the construction program has been agreed then an appropriate reservoir management plan can

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

be drawn up. This should also include the fisheries development plan for the reservoir, along with a recreation and tourism management program for the area.

The reservoir management plan will also have to consider the need for upstream catchment management measures in the watercourses that directly discharge into the reservoir, based upon the results of water quality monitoring that will be carried out. The quality of the reservoir water will also need to be monitored to ensure that there is not a buildup of nutrients that could cause problems with algal growth. If this should start to occur, then adequate measures will need to be taken to prevent nutrient loaded water from flowing into the reservoir.

6.6 IMPACT MONITORING PROGRAM

6.6.1 Objectives of the Impact Monitoring Plan

The objective of the environmental monitoring activities to be carried out during the construction and operation stages of the project will be as follows:

- To monitor the actual project environmental impact on the physical, biological and socioeconomic indicators that will be selected to be appropriate for such work in order to compare appropriate indicators with the situation before the start of the project.
- To provide information that will allow recommend mitigation measures to be drawn up for any unforeseen impact or where the adverse impact level exceeds that anticipated.
- Ensure compliance with legal regulatory requirements and also community obligations, including health and safety at both the construction and operational stages of the project.
- Ensure the safe and environmentally sound disposal of excess construction materials, solid waste and effluents, along with the adequate management of noise and dust emissions.

The main objectives of environmental monitoring during the operation phase will be to:

- Appraise the adequacy of the ESIA with respect to the predicted long-term impacts of the project on the physical, biological and socio-economic environment of the area.
- Evaluate the effectiveness of the mitigation measures proposed in the EMMP and recommend any improvements in the EMMP if they are found to be required.
- Compile periodic incident and accident data to support analyses that will help to minimize future risks.
- Monitor the survival rate of the proposed vegetation planting program and make appropriate proposals to ensure that balanced mixed age and species stands develop in the area that provide sustainable supplies of fruit, fuel-wood and fodder for the local population.

6.6.2 Monitoring Strategy

All the compliance monitoring will be executed by the Contractor during the construction stage of the project to ensure that they operate according to the regulatory framework. Supervision of the

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

compliance environmental monitoring work during the construction stage will be carried out by the Supervisory/Management Consultants (SC).

6.6.3 Monitoring Parameters and Frequency

i) Natural Environment

For the physical environment the following parameters will need to be regularly monitored both before and during construction:

- Ambient air quality (mainly NOx, Sox and CO)
- Batching and crushing plant emissions (smoke, dust, etc.) during operation
- Ambient noise levels
- Water quality (drinking, surface and groundwater), for both chemical composition and also sediment

ii) Socio-economic Environment

The impacts on the socio-economic environment will be monitored by the SC using changes in household economic livelihoods as a major indicator in the longer term. Other key aspects that will need to be monitored include environmental and community health, safety issues, employment availability and generation, along with physical mobility and access, especially for women.

At the construction stage of the project the Supervisory Consultant will maintain a Social Complaints Register. This is an open public document that allows anybody to register a complaint which must then be thoroughly investigated and a judgment made as to its justification and the action need to address the issue.

6.7 CONSTITUTION OF PROJECT ENVIRONMENT MANAGEMENT COMMITTEE

Sr. No.	Agency	Representative	Status
1	WAPDA	Project Director	Chairman
2	Government of GB	DC/ AC (Concerned)	Member
3	Consultant	Resident Engineer	Member
4	Main Contractor	Designated Engineer	Member
5	Environment Department	Director, EPA GB Representative	Member
6	Local Government	Chairman District Council	Member
7	NGO	Representatives of two functional NGOs of the region	Member

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6.8 LAND REQUIREMENTS FOR THE PROJECT

Resettlement, land requirements and acquisition for any mega project is a sensitive task, however, for this project these issues are not as critical as in other projects. Attabad Lake was formed in 2010 as a result of a natural disaster and it still recovers about 4.5 km^2 of land which includes lands of Ainabad, Shishkat, Gulmit and Gulkin. Shishkat, Gulmit and Gulkin are were partly damaged but Ainabad was completely submerged.

Land will be acquired for mostly powerhouse site which includes land powerhouse, switchyard, project colony and project offices. Land at weir site is mostly riverine land and will be acquired from the government. Land required for the Attabad Lake HPP is mentioned in the Table 6-1. Land Requirement for the Project is depicted at **Drawing-II**

Table 6-1: Land Requirements for Attabad Lake HPP

Sr. No.	Description	Town / Village	Land in Acres	Land in Kanals	Land Cost per Kanal (DC Rates)	Remarks
1	Powerhouse Side	Sarat	4	32	750,000	Community Land of Ganish Village
2	Weir and Associated Structures	Attabad	15	120	500,000	Mostly it is riverine land. Left Side of Hunza River is Community Land of Ganish Village and Right Side is Community Land of Attabad Village.
3	Access Roads to Sites	-	-	-	-	Old KKH will be repaired where available and new will be constructed where not available
4	Permanent Project Colony	Sarat	2.5	20	1,500,000	Community Land of Ganish Village
5	Transmission Line	Throughout the T.L route	As per site	As per site	Varies	Land for T.L will be acquired along the route
	Total		**21.5**	**172**		

6.9 ENVIRONMENTAL MITIGATION AND LAND ACQUISITION COST

Land Acquisition and Environmental Mitigation cost have been kept for the cost of permanent land acquisition for project components, temporary land acquisition, building compensation, spoil disposal area rehabilitation, rehabilitation of villages, livelihood allowance for affectees,

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

monitoring & evaluation and land conservation etc. The total cost of land acquisition and environmental mitigation is estimated as Rs. 208.450 Million as shown in Table 6-2

Table 6-2: Cost Estimate for Land Acquisition and Environmental Mitigation

Price Index – March, 2021
US$ Exchange Rate = Rs. 157

Sr. No.	Description	Unit	Qty	Rate	Cost	
				(PKR)	(PKR)	(US$)
1	Permanent Land Acquisition*					
-	Powerhouse Site	kanal	32	750,000	24,000,000	152,866
-	Weir & Associated Structures	kanal	120	750,000	90,000,000	573,248
-	Project Colony	kanal	20	750,000	15,000,000	57,325
-	Miscellaneous	LS	1	16,000,000	16,000,000	101,911
2	Temporary Land Acquisition	LS	1	1,000,000	1,000,000	6,369
3	Building Compensation	LS	1	15,000,000	15,000,000	95,541
4	Spoil Disposal Area Rehabilitation	LS	1	4,000,000	4,000,000	25,478
5	Rehabilitation of Villages	LS	1	2,000,000	2,000,000	12,739
6	Livelihood Allowance for Affectees	LS	1	2,000,000	2,000,000	12,739
7	Monitoring and Evaluation	LS	1	16,500,000	16,500,000	105,096
8	Capacity Building/training	LS	1	2,000,000	2,000,000	12,739
9	Land Conservation	LS	1	2,000,000	2,000,000	12,739
				Sub-Total	**189,500,000**	**1,207,006**
10	Contingencies 10%				18,950,000	120,701
				Total	**208,450,000**	**1,327,707**

Appendix-B-I

Questionnaire for Socio-Environmental Survey (EIA)

(Interview Schedule for Village/Town Profile)

Interviewer_____ Date_____

INTERVIEW LOCATION

Village/Town_____ Union Council_____

Tehsil_____ District_____

---

1. POPULATION

i. Total Population_____
ii. No. of Males_____
iii. No. of Females_____
iv. No. of Children_____

2. ETHIC GROUPS

Major Castes:

i) _____ ii)_____ iii)_____

iv) _____ v)_____ vi)_____

3. HOUSING

i. Total Houses _____
ii. Pacca Houses _____
iii. Mix Houses _____
iv. Katcha Houses _____
v. Total Farm Households _____
vi. Total Landless Household _____

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

4. LANDHOLDINGS

(a) Total Agriculture Land of the Village/Town

i. Land under Cultivation (%age) _____

ii. Land Non-cultivable (%age) _____

(b) Distribution of Farmers by Farm Size

i. No. of Farmers owning Large Farm Size 100 acre

ii. No. of Farmers owning Medium Farm Size 50 acre

iii. No. of Farmers owning Small Farm Size below – 10 acre

(c) Water Supply System source

i) River ii) Irrigation iii) Tube well

iv) Rain Water

5. EDUCATIONAL FACILITIES

School	Type	Available	Available Outside the Village/Town		
		No. of Students	Place	Distance (km)	Approximate No. of student going to
Primary School					
Boys	Govt.				
	Private				
Girls	Govt.				
	Private				
Middle School					
Boys	Govt.				
	Private				
Girls	Govt.				
	Private				
High School					
Boys	Govt.				
	Private				
Girls	Govt.				
	Private

6. CONDITION OF SCHOOLS

Description	Types of Condition		
	Good	Satisfactory	Bad
Boys School			
Building			
Staff Competency			
Student Discipline			
Student Performance			
Student Strength			
Girls School			
Building			
Staff Competency			
Staff Regularity			
Student Strength			
Student Discipline			
Student Performance			

7. HEALTH FACILITIES

Description	Available in Village/Town	Outside the Village/Town	
		Place	Distance (km)
Human Health			
Rural Health Dispensary			
Mother's Child Centre			
Private Doctor			
Lady Health Visitor (LHV)			
TBAs			
Hakim			
Others			
Livestock Health			
Veterinary Hospital/Dispensary			
Other			
Other Basic Facilities			
Post Office			
Bank			
Telephone PCO			
Pacca Link Road			
Clean Drinking Water			
Water Supply Scheme			

8. COMMON DISEASES

i.	Malaria	ii.	Cholera	iii.	Arthritis	iv.	Goiter
v.	Stomach	vi.	TB	vii.	Diabetes	vii.	Any other

Questionnaire for Sociological Survey

(Interview Schedule for Village/Town Profile)

Interviewer _____ Dated _____

Male/Female _____

INTERVIEW LOCATION

Village/Town_____ Union Council_____

Tehsil _____ District_____

_____

1. Project Awareness

i) Have you heard about Attabad Lake Hydropower Project

Yes _____ No_____(Tick the Applicable).

ii) How did you learn about it?

Radio/TV_____ Relatives _____

Newspapers_____ (other specify)_____

iii) What do you know about the Project?

_____

PUBLIC PROCUREMENT REGULATORY AUTHORITY (PPRA) EPADS

2. Household Details of Respondents

Enter details of household

Sr. No.	Name	Position in family	Age/ Year	Occupation	Highest Level of Edu achieved	Vaccination Y N	Resident house	If No, Where Living	This land	Other Land	Reason work

PUBLIC PROCUREMENT REGULATORY AUTHORITY (PPRA) EPADS

3. Land Holdings of Respondents

List: The areas of land that you occupy

Place	Location (Name of village/Town)	Size Acre	Owned Y or N	Distance from main area	If not owned temporary basis			
					Share crop	Rent	Other specify	Rent Paid

4. House of Respondents

House details	Area (ft^2)	Constructed area (ft^2)	Room Nos.	Constructed Form	
				Kacha	Pacca

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

5. Food & Agriculture of Respondents

5.1 Main Area

i) Crop (given area in Area)

Crop Name Rabi/Kharif	Machinery use of animals use for harvesting the crop	Irrigated (kg)				Barrani (kg)			
		Area	Harvested	Sold	Bought	Area	Harvested	Area	Bought

ii) Fruit Trees or Tree Crops in Village/Town

Indicate harvested, sold & bought yield in kg.

Fruit Trees	Nos.	Harvested	Sold	Bought

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

iii) Live Stock of Respondents

Live Stocks	Current	Sold	Bought
Bull			
Cow			
Calves			
Horses			
Mules/Donkeys			
Goats			
Sheep			
Poultry			
Ducks			

5.2 **Area Number for crops in acre.**

Crops Name	Irrigated (kg)				Barrani (kg)			
Rabi/Kharif	Area	Harvested	Sold	Bought	Area	Harvested	Area	Bought

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

6. Living Standard Survey of Respondents

Which of the following items do you have?

Item No.		
1.	Refrigerator	
2.	Deep Freezer	
3.	Television	
4.	Washing Machines	
5.	Geyser	
6.	Electric Fan	
7.	Electric Iron	
8.	Sewing Machine	
9.	Radio/Tape Recorder	
10.	Bicycle	
11.	Motor Cycle/Scooter	
12.	Rickshaw	
13.	Dish Antenna	
14.	Telephone	
15.	Air Cooler	
16.	Power Generator	
17.	Tractor	
18.	Truck	
19.	Tractor Trolley	
20.	Electric Water Pump	

6.1 Living Expenditure Estimates of Respondents

i) Agriculture (yearly estimates)

Item	Cost Rs.
Seed	
Bagged Inorganic Fertilizer	
Crop Agrochemicals herbicides insecticides	
Live stock, agrochemicals	
Hired Labour from location	

ii) Food Expenses of Respondents

Item	Cost Rs.
Meet/Beef/Chicken	
Milk	
Eggs	
Ghee/Butter	
Flour	
Rice	
Fish (Fresh from river)	
Fertile/Pulses/Grams	
Other Specify	

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

iii) Household (non food) expenses (average for month) of Respondents

Item	Cost Rs.
Washing Soap (Powder)	
Bathing Soap/Slopes	
Kerosene Oil	
Forest Wood for cooking	
Electricity	
Telephone	
Other specify	

iv) Clothing Shoe expenses (for family) during the month of Respondents

Item	Cost Rs.
Winter (Last)	
Summer (Last)	

v) Education expenses average for year Rs._____

vi) No. of boys attending school No. of girls _____

vii) Health Expenses (average for year) Rs._____

viii) Transportation Cost average/month Rs._____

ix) Govt. Taxes (average for year) Rs._____

7. Borrowings Facilities

Last year did you borrow money

i) Yes _____ or No _____

If yes

a. How much did you borrow?

b. For what purpose was the money borrowed?

c. Source of Borrow?

d. How much has been paid back?

1. None 2. On quarter 3. One half paid

4. Three quarters 5. All

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

8. Health

What are some of the common diseases occurring in your family during the last year.

		Place where treatment sought (click for each disease)									
Gender	Disease	None	Dr./Hospital	MCH Centre	Dispensary	Hakeem	Pir/Moulvi/Sufi	Pharmacist	Medical Store	Homeopath	Other specify
Men											
Women											
Children											

9. Child Birth

9.1 How many of your children were born at hospital

9.2 How many children were born at home

9.3 Who delivered the last baby born? was it any of the following (Tick 1)

i) Traditional _____

ii) TBA _____

iii) Doctor _____

iv) Other Specify _____

10. Forest

i) Do you own trees/Forests? Yes / No

If Yes, No. of forest trees _____

ii) Did you plant any tree last year? Yes / No

If Yes, how many did you plant and name of trees _____

iii) How many trees did you cut down last year? _____

iv) Why did you cut these down? _____

v) How much money did you get from tree sales? _____Rs. (last year)

vi) How much fuel wood do you need per day for domestic purposes ____kg/day

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

vii) Where do you harvest this fuel wood?

Location, distance to carry _____

viii) Do you gather other forest products? If yes what are these.

ix) Did you sell any forest products last year? If so how much money did you earn _____Rs.

11. River & Water Supply Usage

i) For which of the following purpose do you use River and Water Supply? Choose multiple options for more than one answer.

1) Fish (if yes) 2) Washing/Bathing 3) Drinking

4) Other uses specify

ii) If you do not use the river water, what are your water supply sources?

1) Spring 2) Well 3) Pumped groundwater

4) Public stand Pipe 5) Hand Pump 6) Other specify

iii) How much far do you have to travel to fetch water for daily use? _____km

iv) Who fetches water mostly? Husband/Wife Daughter/Son Male/Female

12. River Flow Reduction in Hunza River

12.1 If the project reduced the river flow, Is this concern you? Yes/No

If Yes why _____

13. Fishing

i) Name the water source where your catch fish? _____

ii) How much times you catch fish in a week? (summer/winter) _____

iii) What is your purpose for catching fishing? _____

iv) How much do you normally catch per week (summer/winter) _____kg.

v) What fishing gear do you use?

Net _____ Hand line_____ Trap_____ Other specify

vi) Do you sell fish? Yes / No

If Yes, location where you sell your catch _____?

vii) How much of your caught fish do you able sell each week? _____kg.

viii) What is value of this sale of caught fish per day? _____Rs.

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

14. Alternative Income sources & development requirement.

14.1 Are you satisfied with your living conditions Yes / No

If yes why_____

14.2 In your opinion what kinds of development projects/improvements are needed for this area. please explain your reasons.

15. General Resettlement Concerns

15.1 If the project proceeds, some people may be relocated. If this happens what beneficial/adverse effects do you consider, the Project would have on the following:

Question	Beneficial	Adverse
On your farming		
On your livestock of grazing		
On your family		
On your village community		
Other specify		

15.2 In case you will have to move, do you have any place where you could move?

15.3 Location and distance from your present residence.

Appendix- B-3

Questionnaire for Women Survey

(Interview Schedule for Village/Town Profile)

Interviewer _____ Dated _____

Name Female _____ Age _____years

INTERVIEW LOCATION

Village/Town_____ Union Council_____

Tehsil _____ District_____

1. What is your marital status? Single / Married
2. How many children do you have? _____boys _____girls
3. At what age you were married? _____years
4. Family size
5. What is your Education?
6. What is your occupation?
   a. Job (if yes, specify_____)
   b. Housewife
   c. Student (if yes, then level _____ and education institute _____)
7. Role of women in decision making?
8. Diseases
9. Early age marriages
10. Medical facilities for women
11. In your opinion, which steps should be taken for uplifting of women social status?

e-Pak Acquisition and Disposal System (EPADS) generated document | © 2026

12. Do you know or have an idea of project?

13. In case, compensation will give to you, where do you want to live

(near village/or another big city)

14. If vocational training institute is opened for women's social uplifting then which of the following setup would you prefer?

a. Fruits or vegetables preserve factory
b. Livestock
c. Fish Packaging Setup

15. Do your children go to school? Yes/No

If No then why? _____

If yes then which level _____ School name_____

16. Does your Daughter go to School? Yes/No

If No then why? _____

If yes then which level _____ School name_____

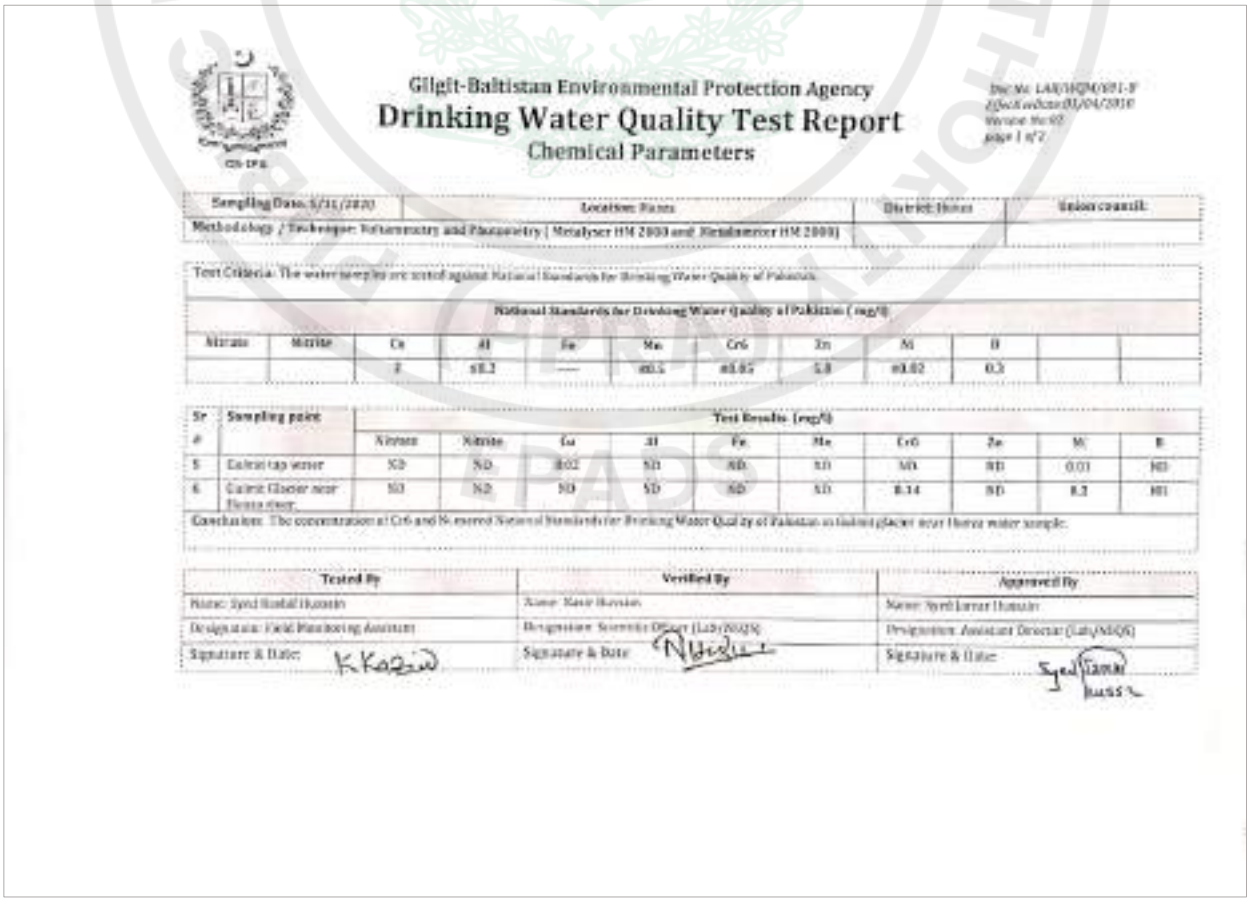
GB-EPA

Sampling Date: 5/11/2020	Location: Hunza	District: Hunza	Union council:
Methodology / Technique: Voltammetry and Photometry (Metalyser HM 3000 and Metalmeter HM 2000)			

Test Criteria: The water samples are tested against National Standards for Drinking Water Quality of Pakistan



National Standards for Drinking Water Quality of Pakistan (mg/l)

Nitrate	Nitrite	Cu	Al	Fe	Mn	Cr6	Zn	Ni	B		
<50	≤3	2	≤0.2	----	≤0.5	≤0.05	5.0	≤0.02	0.3		

Sr #	Sampling point	Test Results (mg/l)									
		Nitrate	Nitrite	Cu	Al	Fe	Mn	Cr6	Zn	Ni	B
1	Hunza River side before confluence of Ghamubar Nullah	ND	ND	0.1	ND	ND	ND	0.03	ND	0.01	ND
2	Ghamubar Nullah by entering Hunza	ND	ND	0.07	ND	0.04	ND	0.02	ND	0.02	ND
3	Hunza River side near power house	ND	ND	0.2	ND	0.3	ND	ND	ND	0.01	ND
4	Attabad lake boating area	2.3	0.3	ND	ND	ND	ND	0.02	ND	0.02	ND

Conclusion: The concentrations of nitrate, copper, iron, chromium & nickel in above samples are within National Standards for Drinking Water Quality of Pakistan.

Drinking Water Quality Test Report
Bacteriological and Physical Parameters

Doc No: LAB/WQM/001-A
Effective Date: 01/04/2018
Version No:02
page 1 of 1

Sampling Date: 5/11/2018	Location: Hunza	District: Hunza	Union council:
Methodology / Technique: Membrane Filtration Technique [MF]			

Test Criteria: The water samples are tested against National Standards for Drinking Water Quality of Pakistan

Bacteriological Parameters	National Standards for Drinking Water Quality of Pakistan (Physical Parameters)						
E.coli	pH	Turbidity	Total Dissolved Solids	Electrical Conductivity	Colour	Odour	Taste
0/100 ml	6.5-8.5	< 5NTU	< 1000 ppm	2000 µS	Un Objectionable	Un Objectionable	Un Objectionable

Sr#	Sampling Point	Test Results: Bacteriological Parameters	Physical Parameters						
		E.coli	pH	Turbidity	Total Dissolved Solids	Electrical Conductivity	Temp.	Colour	Odour	Taste
1	Hunza River side before confluence of Shimshal Nullah	3 col/100ml	8.4	<5 NTU	67.8 ppm	139.4 µS	7°C	Clear	Odourless	Tasteless
2	Shimshal Nullah by entering Hunza	0 col/100ml	8.4	15 NTU	98.1 ppm	186.8 µS	7°C	Clear	Odourless	Tasteless
3	Hunza river side near power house	0 col/100ml	8	<5 NTU	62.7 ppm	125.4 µS	7°C	Clear	Odourless	Tasteless
4	Aliabad bus barring area	0 col/100ml	8.3	<5 NTU	65.4 ppm	129.7 µS	7°C	Clear	Odourless	Tasteless

Conclusion: Results shows that the turbidity in Shimshal Nullah by entering Hunza water samples exceed the National Standards for Drinking Water Quality of Pakistan
